Numerical approach to a model for quasistatic damage with spatial BV-regularization

Sören Bartels, Marijo Milicevic, and Marita Thomas

Abstract We address a model for rate-independent, partial, isotropic damage in quasistatic small strain linear elasticity, featuring a damage variable with spatial BV-regularization. Discrete solutions are obtained using an alternate time-discrete scheme and the *Variable*-ADMM algorithm to solve the constrained nonsmooth optimization problem that determines the damage variable at each time step. We prove convergence of the method and show that discrete solutions approximate a semistable energetic solution of the rate-independent system. Moreover, we present our numerical results for two benchmark problems.

1 The damage model, its solution concept, and our results

By damage evolution we understand the formation and growth of cracks and voids in the microstructure of a solid material. This process is monitored over a time interval $[0,\mathsf{T}]$ for a body with reference configuration $\Omega \subset \mathbb{R}^d$, $d > 1$. In the spirit of generalized standard materials [29] and continuum damage mechanics [34, 35] this degradation phenomenon is modeled by a volumetric internal damage variable $z : [0,\mathsf{T}] \times \Omega \to [0,1]$ which is incorporated into the constitutive law in order to reflect the changes of the elastic behavior due to damage. It is assumed that the length scale

of the specimen of the considered material is much larger than that of the respective *reference volume*. The reference volume of a material is a characteristic volume such that all relevant properties of the material are comprised in this amount of material and such that the material can be regarded as homogeneous if it is considered in a much larger length scale than the length scale of the reference volume. The value $z(t,x)$ at $(t,x) \in [0,T] \times \Omega$ can then be understood as the undamaged fraction of the reference volume at time t located in $x \in \Omega$.

The evolution of the damage variable is driven by time-dependent external loads, which cause the deformation of the body and increase its stresses. To relax, damage evolves and thus turns stored energy into dissipated energy. These two energy contributions can be described by an energy functional $\mathscr{E}$ and a dissipation potential $\mathscr{R}$. In literature many different assumptions have been made with regard to the growth properties of the two functionals, which directly affect the regularity properties of the damage variable with regard to time and space. In this way the contributions to damage processes in mathematical and engineering literature can be divided into two major classes: One class considers the evolution of damage as a rate-dependent phaenomenon, mostly modeled by a viscous dissipation with quadratic growth, cf. e.g. [20, 19, 31, 7, 8, 49] and a further class understands damage as a rate-independent process described by a positively 1-homogeneous dissipation potential, cf. e.g. [30, 37, 11, 17, 45, 59, 57, 58]. While the first growth property leads comparably smooth evolution in time settled in $L^2(\Omega)$, the latter only provides bounded variations in time, so that the damage variable may jump in time. Indeed, the use of a rate-independent model, resp. the neglection of rate-effects, is also seen as a feasible approximation for certain damage processes observed in experiments, cf. e.g. [27]. We will follow the latter concept and consider the 1-homogeneous dissipation potential $\mathscr{R} : \mathbf{Z} \to \mathbb{R} \cup \{\infty\}$,

$$\mathscr{R}(v) := \int_\Omega \mathrm{R}(v)\,\mathrm{d}x, \quad \text{with } \mathrm{R}(v) := \begin{cases} \rho|v|\,\mathrm{d}x & \text{if } v \in (-\infty, 0], \\ +\infty & \text{if } v > 0 \end{cases} \tag{1a}$$

$$\text{with } \mathbf{Z} := L^1(\Omega)\,, \tag{1b}$$

and with a constant dissipation rate $\rho > 0$. Due to the convention $z = 1$ for the unbroken and $z = 0$ for the broken state of the material, the dissipation potential ensures the unidirectionality of the process and thus prevents healing of the material. Also for the energy functional $\mathscr{E}$ different regularity assumptions have been made for the damage variable: By now, it has bekome a well-accepted approach to incorporate damage gradients into the energy, in order to account for nonlocal effects of damage from a physical point of view, and to benefit from its regularizing effect in the mathematical analysis and numerical simulations. The vast majority of contributions considers a damage gradient with growth of power $p = 2$ [20, 19, 28, 7, 8, 42, 40, 60, 56, 2, 39, 36]. For technical reasons, sometimes also $p > d$ is chosen, cf. e.g. [44, 31, 49]. It has to be remarked that this choice has direct influence on the effects of damage that can be observed with this model: For gradient regularizations of this type, mathematically, the damage variable is an element in

a Sobolev space, and transitions between damaged and undamaged material phases have to be smooth and thus have to take place in zones of a certain positive width. The assumption $p > d$ enforces that the damage variable even has to be continuous in space. Yet, from own experience one can also observe situations where the transition between damaged and undamaged regions is very sharp. This effect cannot be described by a regularization in Sobolev spaces. Therefore it is the aim of this work to contribute to the toolbox for the investigation of damage processes with a model that allows for sharp transitions between damaged and undamaged material phases. To capture this effect, but still to benefit from regularizing effects of gradients, we propose to replace the Sobolev-gradient by a BV-gradient. More precisely, we shall consider an energy functional $\widehat{\mathscr{E}} : [0,\mathsf{T}] \times \mathbf{U} \times \mathbf{X} \to \mathbb{R} \cup \{\infty\}$ of the form

$$\begin{aligned}\widehat{\mathscr{E}}(t,u,z) := \frac{1}{2}\int_\Omega f(z)\big(\lambda\,|\operatorname{tr} e(u+g(t))|^2 + 2\mu|e(u+g(t))|^2\big)\,\mathrm{d}x \\ + \kappa|\,\mathrm{D}z|(\Omega) + \int_\Omega I_{[0,1]}(z)\,\mathrm{d}x - \int_{\Gamma_\mathrm{N}} u_\mathrm{N}(t)\cdot(u+g(t))\,\mathrm{d}s\end{aligned} \tag{2}$$

with the Lamé constants $\lambda, \mu > 0$, $e(u) := \frac{1}{2}(\nabla u + \nabla u^\top)$ the small-strain tensor, $g : [0,\mathsf{T}] \times \Omega \to \mathbb{R}^d$ a suitable extension of a given Dirichlet datum into the domain Ω and $u_\mathrm{N} : [0,\mathsf{T}] \times \Gamma_\mathrm{N} \to \mathbb{R}^d$ a given surface loading acting along the Neumann-boundary Γ_N. Due to the mapping properties of the monotonously increasing function $f : [0,1] \to [a,b]$ with constants $0 < a < b$ the model will capture partial damage only: It is $f(0) \geq a$ and hence, even in the state of maximal damage the solid has the ability to counteract external loadings with suitable stresses and displacements; for models allowing for complete damage, where this property is lost, we refer e.g. to [9, 46, 32]. The compactness information needed to handle the product of $f(z)$ and quadratic terms in e is provided by the total variation $|\,\mathrm{D}z|(\Omega)$ of z in Ω, weigthed with a constant $\kappa > 0$,. Finally, the indicator function $I_{[0,1]}$ confines the values of z to the interval $[0,1]$, i.e., $I_{[0,1]}(z) = 0$ if $z \in [0,1]$ and $I_{[0,1]}(z) = \infty$ otherwise. In view of (2) we set

$$\mathbf{U} := \{v \in H^1(\Omega,\mathbb{R}^d),\, v = 0 \text{ on } \Gamma_D \text{ in trace sense}\}, \tag{3a}$$

$$\mathbf{X} := \mathrm{BV}(\Omega), \tag{3b}$$

so that, in view of (1b), we will work with the extended energy functional $\mathscr{E} : [0,\mathsf{T}] \times \mathbf{U} \times \mathbf{Z} \to \mathbb{R} \cup \{\infty\}$

$$\mathscr{E}(t,u,z) := \begin{cases} \widehat{\mathscr{E}}(t,u,z) & \text{if } (u,z) \in \mathbf{U} \times \mathbf{X}, \\ \infty & \text{otherwise.} \end{cases} \tag{4}$$

It is the aim of this paper to study the existence of solutions for the rate-independent system $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}, \mathscr{R})$ given by (3), (4), (1a) by proving the convergence of a numerical method. For this, we will impose a partition $\Pi_N := \{t_N^k,\, k \in \{0,1,\ldots,N\}, 0 = t_N^0 < \ldots < t_N^N = \mathsf{T}\}$ of the time-interval $[0,\mathsf{T}]$ and a space discretization in terms of $P1$ finite elements, yielding finite-element spaces $\mathbf{U}_h, \mathbf{X}_h$. At each time-step $t_N^k \in \Pi_N$,

we will determine approximate solutions in $\mathbf{U}_h, \mathbf{X}_h$ via an alternating minimization scheme, i.e., starting from an approximation $(u_{0h}, z_{0h}) \in \mathbf{U}_h \times \mathbf{X}_h$ of the initial datum (u_0, z_0) at t_N^0, we alternatingly compute

$$u_{Nh}^k = \operatorname{argmin}_{u \in \mathbf{U}_h} \mathscr{E}(t_k, u, z_{Nh}^{k-1}), \tag{5a}$$

$$z_{Nh}^k \in \operatorname{argmin}_{z \in \mathbf{X}_h} \mathscr{E}(t_k, u_{Nh}^k, z) + \mathscr{R}(z - z_{Nh}^{k-1}). \tag{5b}$$

While the computation of u_{Nh}^k reduces to the solution of a linear system of equations, the computation of z_{Nh}^k requires the solution of a constrained nonsmooth minimization problem. This problem is qualitatively of the form of the Rudin-Osher-Fatemi (ROF) problem [55] for which various numerical schemes have been proposed for its iterative solution, cf., e.g., [3, 6, 13, 14, 25, 26, 33, 38, 50, 62]. We approximate a minimizer z_{Nh}^k by converting the minimization problem into a saddle-point problem and use a variant of the alternate direction method of multipliers (ADMM) [18, 21, 22, 23, 24] recently introduced in [5] as *Variable-ADMM* for the approximate solution of the saddle-point problem.
As $N \to \infty$ for the time-discretization and $h \to 0$ for the space-discretization we show that suitable interpolants constructed from (5) approximate a semistable energetic solution of the system $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}, \mathscr{R})$:

Definition 1.1 (semistable energetic solution). A function $q = (u, z) : [0, \mathsf{T}] \to \mathbf{U} \times \mathbf{Z}$ is called semi-stable energetic solution for the system $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}, \mathscr{R})$, if $t \to \partial_t \mathscr{E}(t, q) \in L^1((0, \mathsf{T}))$ and if for all $s, t \in [0, \mathsf{T}]$ we have $\mathscr{E}(t, q(t)) < \infty$, if for a.a. $t \in (0, \mathsf{T})$ minimality condition (6a) is satisfied and if for all $t \in [0, \mathsf{T}]$ semistability (6b) as well as the upper energy-dissipation estimate (6c) hold true, i.e.:

$$\text{for all } \tilde{u} \in \mathbf{U}: \quad \mathscr{E}(t, u(t), z(t)) \le \mathscr{E}(t, \tilde{u}, z(t)), \tag{6a}$$

$$\text{for all } \tilde{z} \in \mathbf{X}: \quad \mathscr{E}(t, u(t), z(t)) \le \mathscr{E}(t, u(t), \tilde{z}) + \mathscr{R}(\tilde{z} - z(t)), \tag{6b}$$

$$\mathscr{E}(t, q(t)) + \mathscr{R}(z(t) - z(0)) \le \mathscr{E}(0, q(0)) + \int_0^t \partial_\xi \mathscr{E}(\xi, q(\xi))\, \mathrm{d}\xi, \tag{6c}$$

where the dissipated energy up to time t is given by the total variation induced by the dissipation potential $\mathscr{R}$ with unidirectionality constraint and, by thus induced monotonicity of $z : [0, \mathsf{T}] \to \mathbf{Z}$, takes the form $\mathscr{R}(z(t) - z(0))$.

Let us note here that the alternate minimization scheme (5) directly leads to the notion of semistable energetic solutions. In the quasistatic, rate-independent setting they form a much wider class than the well-known energetic solutions, cf. e.g. [43, 45], which replace conditions (6a) & (6b) by the joint global stability condition $\forall (\tilde{u}, \tilde{z}) \in \mathbf{U} \times \mathbf{Z} : \mathscr{E}(t, u(t), z(t)) \le \mathscr{E}(t, \tilde{u}, \tilde{z}) + \mathscr{R}(\tilde{z} - z(t))$ and the upper energy-dissipation estimate (6c) by an energy-dissipation *balance*. In fact, the existence of energetic solutions for the above system $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}, \mathscr{R})$ was investigated in [57]. As a matter of concept, energetic solutions are obtained from a time-discrete scheme with a monolithic minimization in the pair (u, z) in each time step. In the case that $\mathscr{E}(t, \cdot, \cdot)$ is jointly convex in the pair (u, z) it can be shown that semistable energetic solutions are also energetic solutions. However, this is not true if the energy func-

tional does not enjoy the property of joint convexity. In this case it can be observed that energetic solutions tend to evolve earlier than semistable energetic solutions, cf. e.g. [52]. Indeed, many energy functionals taken from engineering literature are separately convex in the variables u and z but not jointly convex, cf. [59, Sec. 5] for examples on convexity properties of damage models.

Our paper is organized as follows: In Section 2 we state the main assumptions needed for the analysis. Section 3 introduces the numerical algorithms used to calculate approximate solutions in the sense of (5). We present the Variable-ADMM adjusted to the present setting, address its stability and the monotonicity of the residual and prove that the residual controls the difference between the optimal energy and the energy of the iterates. Based on this, in Section 4 we prove our main result, Thm. 4.1, providing the convergence of the approximate solutions to a semistable energetic solution of $(\mathbf{U}\times\mathbf{Z},\mathscr{E},\mathscr{R})$ in the sense of evolutionary Γ-convergence. Finally, in Section 5 we report our numerical results for an academic example and a benchmark problem from engineering.

2 Setup and notation

Throughout this work, we consider the time interval $[0,\mathsf{T}]$ for some time horizon $\mathsf{T}>0$ and an open bounded Lipschitz domain $\Omega\subset\mathbb{R}^d$, $d=2,3$, with Dirichlet boundary $\Gamma_D\subset\partial\Omega$ with positive $(d-1)$-dimensional Hausdorff-measure $\mathscr{H}^{d-1}(\Gamma_D)>0$. We denote by $(\cdot,\cdot)$ the L^2-inner product, by $\|\cdot\|$ the L^2-norm, and by $|\cdot|$ the Euclidean norm on $\mathbb{R}^d$. Moreover, by $\mathrm{B}([0,T],\bullet)$ we denote the space of functions f mapping time into a space $\bullet$, which are bounded and defined everywhere in $[0,T]$. Regarding the given data appearing in (2) we make the following assumptions:

Assumption 2.1 (Assumptions on the given data) *1. The function $f:[0,1]\to[a,b]$ is continuously differentiable, convex, and monotonically increasing.*
2. The Lamé constants satisfy $\lambda,\mu>0$.
3. The extension of the Dirichlet datum is of regularity $g\in C^1([0,\mathsf{T}],H^1(\Omega;\mathbb{R}^d))$ with $C_g:=\|g\|_{C^1([0,\mathsf{T}],H^1(\Omega;\mathbb{R}^d))}$.
4. The Neumann datum u_{N} is of regularity $u_{\mathrm{N}}\in C^1([0,\mathsf{T}],L^2(\Gamma_{\mathrm{N}};\mathbb{R}^d))$ with $C_{u_{\mathrm{N}}}:=\|u_{\mathrm{N}}\|_{C^1([0,\mathsf{T}],L^2(\Gamma_{\mathrm{N}};\mathbb{R}^d))}$

Moreover, for the space discretization we will use the following notation related to **finite element spaces**: Let $(\mathscr{T}_h)_{h>0}$ be a family of triangulations of Ω where the index h denotes the mesh size $h=\max_{T\in\mathscr{T}_h}h_T$ with h_T being the diameter of the simplex T. The minimal diameter is given by $h_{\min}=\min_{T\in\mathscr{T}_h}h_T$. The sets $\mathscr{N}_h$ and E_h contain all nodes and edges, respectively, of the triangulation $\mathscr{T}_h$. We will use the finite element space of continuous, piecewise affine functions ($r=1$) or vector fields ($r=d$), denoted by $\mathscr{S}^1(\mathscr{T}_h)^r$ and of elementwise constant vector fields $\mathscr{L}^0(\mathscr{T}_h)^d$, i.e.,

$$\mathscr{S}^1(\mathscr{T}_h)^r := \{v_h \in C(\Omega;\mathbb{R}^r) : \ v_h|_T \text{ affine for all } T \in \mathscr{T}_h\}, \tag{7a}$$
$$\mathscr{L}^0(\mathscr{T}_h)^d := \{q_h \in L^\infty(\Omega;\mathbb{R}^d) : \ q_h|_T \text{ constant for all } T \in \mathscr{T}_h\}. \tag{7b}$$

Moreover, denoting by $\mathscr{I}_h : C^0(\overline{\Omega}) \to \mathscr{S}^1(\mathscr{T}_h)$ the standard nodal interpolation operator we will consider the discrete inner products

$$(v_h, w_h)_h := \int_\Omega \mathscr{I}_h[v_h w_h]\,\mathrm{d}x = \sum_{y\in\mathscr{N}_h} \beta_y v_h(y) w_h(y) \quad \text{on } \mathscr{S}^1(\mathscr{T}_h),$$
$$(p_h, q_h)_w := h_{\min}^d (p_h, q_h) \quad \text{on } \mathscr{L}^0(\mathscr{T}_h)^d,$$

where $\beta_y = \int_\Omega \varphi_y \,\mathrm{d}x$ with φ_y the nodal basis function associated to $y \in \mathscr{N}_h$. We have the relations

$$\|v_h\| \le \|v_h\|_h \le (d+2)^{1/2}\|v_h\|, \quad \text{and} \quad \|q_h\|_w \le c\|q_h\|_{L^1(\Omega)},$$

for all $v_h \in \mathscr{S}^1(\mathscr{T}_h)$ and $q_h \in \mathscr{L}^0(\mathscr{T}_h)^d$, see [4, Lemma 3.9] and [12, Thm. 4.5.11]. Finally, for a sequence of step sizes $(\tau_j)_{j\in\mathbb{N}}$ and functions $(a^j)_{j\in\mathbb{N}}$ we will denote the backward difference quotient by

$$d_t a^j = \frac{a^j - a^{j-1}}{\tau_j}.$$

3 Numerical Method

We now discuss the numerical algorithms used to solve the alternate minimization problem (5) on the discrete level. With $\mathscr{S}^1(\mathscr{T}_h)^d$ and $\mathscr{S}^1(\mathscr{T}_h)$ from (7) we set $\mathbf{U}_h := \mathscr{S}^1(\mathscr{T}_h)^d \cap \{v \in C(\overline{\Omega};\mathbb{R}^d), v = 0 \text{ on } \Gamma_D\} \subset H^1_D(\Omega;\mathbb{R}^d)$ in (5a) and $\mathbf{X}_h := \mathscr{S}^1(\mathscr{T}_h) \subset BV(\Omega)$ in (5b). While the minimization problem (5a) to determine u^k_{Nh} reduces to the solution of a linear system of equations, the minimization problem (5b) to find z^k_{Nh} is more difficult due to the non-differentiability of the BV-seminorm and the occurence of non-smooth constraints in $\mathscr{E}$ and $\mathscr{R}$. We will deal with the minimization problem (5b) in Subsection 3.1 and subsequently explain the algorithm for the full alternate minimization problem in Subsection 3.2.

3.1 Minimization with respect to z in (5b)

For the following discussion we consider a partition Π_N of $[0,\mathsf{T}]$ with $N \in \mathbb{N}$ fixed. We also keep $t^k_N \in \Pi_N$ and u^k_{Nh} the solution of (5a) fixed. For simpler notation we here write $t_k = t^k_N$, $u^k_h = u^k_{Nh}$, and $z^k_h = z^k_{Nh}$, i.e. we do not indicate the dependence of these quantities on $N \in \mathbb{N}$ fixed. We first of all note that a minimizer $z^k_h = z^k_{Nh}$ obtained in (5b) is required to satisfy $z^k_h - z^{k-1}_h \le 0$ almost everywhere in Ω since

otherwise $\mathscr{R}(z_h^k - z_h^{k-1})$ is infinite. Since $z_h^k, z_h^{k-1} \in \mathbf{X}_h = \mathscr{S}^1(\mathscr{T}_h)$ are globally continuous and piecewise affine this is equivalent to $z_h^k(x) \le z_h^{k-1}(x)$ for all $x \in \mathscr{N}_h$. Particularly, $|z_h^k(x) - z_h^{k-1}(x)| = z_h^{k-1}(x) - z_h^k(x)$. Hence, letting for $k \ge 1$

$$K_k := \{v_h \in \mathscr{S}^1(\mathscr{T}_h) : \ 0 \le v_h(x) \le z_h^{k-1}(x) \ \forall\, x \in \mathscr{N}_h\} \tag{8}$$

we define the auxiliary functional $\widetilde{\mathscr{E}}(t_k, \cdot, \cdot) : \mathbf{U}_h \times \mathbf{X}_h \to \mathbb{R} \cup \{\infty\}$,

$$\begin{aligned}\widetilde{\mathscr{E}}(t_k, u_h, z_h) := \frac{1}{2}\int_\Omega f(z_h)\big(\lambda\,|\operatorname{tr} e(u_h + g(t_k))|^2 + 2\mu |e(u_h + g(t_k))|^2\big)\,\mathrm{d}x \\ - \int_{\Gamma_N} u_N(t_k)\cdot(u_h + g(t_k))\,\mathrm{d}s + \kappa \int_\Omega |\nabla z_h|\,\mathrm{d}x + I_{K_k}(z_h).\end{aligned}$$

We obtain that minimality property (5b) is equivalent to

$$z_h^k \in \operatorname{argmin}_{z_h \in \mathbf{X}_h} \widetilde{\mathscr{E}}(t_k, u_h^k, z_h) - \rho(z_h, 1).$$

In order to approximate a minimizer z_h^k we consider for $\tau_j > 0$ the augmented Lagrangian functional

$$\begin{aligned}L_h^k(z_h, p_h, s_h; \eta_h, \zeta_h) := \frac{1}{2}\int_\Omega f(z_h) e(u_h^k + g(t_k)) : \mathbb{C} e(u_h^k + g(t_k))\,\mathrm{d}x - \rho(z_h, 1) \\ + \kappa \int_\Omega |p_h|\,\mathrm{d}x + (\eta_h, \nabla z_h - p_h)_w + \frac{\tau_j}{2}\|\nabla z_h - p_h\|_w^2 \\ + I_{K_k}(s_h) + (\zeta_h, z_h - s_h)_h + \frac{\tau_j}{2}\|z_h - s_h\|_h^2.\end{aligned}$$

For the approximation of a minimizer z_h^k we use the following algorithm [5] which generalizes the alternating direction method of multipliers (ADMM) established and analyzed, e.g., in [18, 21, 22, 23, 24], by using variable step sizes.

Algorithm 3.1 (Variable-ADMM) *Choose $z_h^0 = z_h^{k-1}$, $\eta_h^0 = 0$ and $\zeta_h^0 = 0$. Choose $\underline{\tau}, \overline{\tau} > 0$ with $\underline{\tau} \le \overline{\tau}$, $\delta \in (0,1)$, $\underline{\gamma}, \overline{\gamma} \in (0,1)$ with $\underline{\gamma} \le \overline{\gamma}$, and $\overline{R} \gg 1$. Set $j = 1$.*
(1) Set $\gamma_1 = \underline{\gamma}$, $\tau_1 = \overline{\tau}$ and $R_0 = \overline{R}$.
(2) Compute a minimizer $(p_h^j, s_h^j) \in \mathscr{L}^0(\mathscr{T}_h)^d \times \mathscr{S}^1(\mathscr{T}_h)$ of

$$(p_h, s_h) \mapsto L_h^k(z_h^{j-1}, p_h, s_h; \eta_h^{j-1}, \zeta_h^{j-1}).$$

(3) Compute a minimizer $z_h^j \in \mathscr{S}^1(\mathscr{T}_h)$ of

$$z_h \mapsto L_h^k(z_h, p_h^j, s_h^j; \eta_h^{j-1}, \zeta_h^{j-1}).$$

(4) Update

$$\eta_h^j = \eta_h^{j-1} + \tau_j(\nabla z_h^j - p_h^j),$$
$$\zeta_h^j = \zeta_h^{j-1} + \tau_j(z_h^j - s_h^j).$$

(5) Define

$$R_j = \big(\|\eta_h^j - \eta_h^{j-1}\|_w^2 + \tau_j^2\|\nabla(z_h^j - z_h^{j-1})\|_w^2 + \|\zeta_h^j - \zeta_h^{j-1}\|_h^2 + \tau_j^2\|z_h^j - z_h^{j-1}\|_h^2\big)^{1/2}.$$

(6) Stop if R_j is sufficiently small.
(7) Define $(\tau_{j+1}, \gamma_{j+1})$ as follows:

- *If $R_j \le \gamma_j R_{j-1}$ or if $\tau_j = \underline{\tau}$ and $\gamma_j = \overline{\gamma}$ set*

$$\tau_{j+1} = \tau_j \quad \text{and} \quad \gamma_{j+1} = \gamma_j.$$

- *If $R_j > \gamma_j R_{j-1}$ and $\tau_j > \underline{\tau}$ set*

$$\tau_{j+1} = \max\{\delta\tau_j, \underline{\tau}\} \quad \text{and} \quad \gamma_{j+1} = \gamma_j.$$

- *If $R_j > \gamma_j R_{j-1}$, $\tau_j = \underline{\tau}$ and $\gamma_j < \overline{\gamma}$ set*

$$\tau_{j+1} = \overline{\tau},\ \gamma_{j+1} = \min\Big\{\frac{\gamma_j+1}{2}, \overline{\gamma}\Big\},\ u^j = u^0 \text{ and } \lambda^j = \lambda^0.$$

(8) Set $j = j+1$ and continue with (2).

In the following proposition we prove that the iterates are bounded, that the algorithm terminates and that the residuals R_j are monotonically decreasing. To this extent we define the functionals

$$F(p_h) = \kappa\int_\Omega |p_h|\,\mathrm{d}x, \quad H(s_h) = I_{K_k}(s_h),$$
$$G(z_h) = \frac{1}{2}\int_\Omega f(z_h)e(u_h^k + g(t_k)) : \mathbb{C}e(u_h^k + g(t_k))\,\mathrm{d}x - \rho(z_h, 1).$$

Proposition 3.1 (Termination of Alg. 3.1 and monotonicity of residuals). *Let $(z_h, p_h, s_h; \eta_h, \zeta_h)$ be a saddle-point for L_h^k. For the iterates $(z_h^j, p_h^j, s_h^j; \eta_h^j, \zeta_h^j)$, $j \ge 0$, of Algorithm 3.1, the corresponding differences $\delta_\eta^j := \eta_h - \eta_h^j$, $\delta_\zeta^j := \zeta_h - \zeta_h^j$, $\delta_p^j := p_h - p_h^j$, $\delta_s^j := s_h - s_h^j$, and $\delta_z^j := z_h - z_h^j$, and the distance*

$$D_j^2 = \|\delta_\eta^j\|_w^2 + \|\delta_\zeta^j\|_h^2 + \tau_j^2\|\nabla\delta_z^j\|_w^2 + \tau_j^2\|\delta_z^j\|_h^2,$$

we have that for every $J \ge 1$ it holds

$$D_J^2 + \sum_{j=1}^J R_j^2 \le D_0^2.$$

In particular, $R_j \to 0$ as $j \to \infty$ and Algorithm 3.1 terminates. Moreover, we have

$$R_{j+1}^2 \le R_j^2,$$

i.e., the residual is non-increasing.

Proof. The optimality conditions for a saddle-point of L_h^k are given by

$$\begin{aligned} (\eta_h, q_h - p_h)_w + F(p_h) &\le F(q_h) \quad \forall\, q_h \in \mathscr{L}^0(\mathscr{T}_h)^d, \\ (\zeta_h, r_h - s_h)_h + H(s_h) &\le H(r_h) \quad \forall\, r_h \in \mathscr{S}^1(\mathscr{T}_h), \\ -(\eta_h, \nabla(w_h - z_h))_w - (\zeta_h, w_h - z_h)_h + G(z_h) &\le G(w_h) \quad \forall\, w_h \in \mathscr{S}^1(\mathscr{T}_h), \end{aligned} \tag{9}$$

and $p_h = \nabla z_h$ and $s_h = z_h$. On the other hand, with $\widetilde{\eta}_h^j = \eta_h^{j-1} + \tau_j(\nabla z_h^{j-1} - p_h^j)$ and $\widetilde{\zeta}_h^j = \zeta_h^{j-1} + \tau_j(z_h^{j-1} - s_h^j)$, the optimality conditions for the iterates of Algorithm 3.1 read

$$\begin{aligned} (\widetilde{\eta}_h^j, q_h - p_h^j)_w + F(p_h^j) &\le F(q_h) \quad \forall\, q_h \in \mathscr{L}^0(\mathscr{T}_h)^d, \\ (\widetilde{\zeta}_h^j, r_h - s_h^j)_h + H(s_h^j) &\le H(r_h) \quad \forall\, r_h \in \mathscr{S}^1(\mathscr{T}_h), \\ -(\eta_h^j, \nabla(w_h - z_h^j))_w - (\zeta_h^j, w_h - z_h^j)_h + G(z_h^j) &\le G(w_h) \quad \forall\, w_h \in \mathscr{S}^1(\mathscr{T}_h). \end{aligned} \tag{10}$$

Testing (9) and (10) with $(q_h, r_h, w_h) = (p_h^j, s_h^j, z_h^j)$ and $(q_h, r_h, w_h) = (p_h, s_h, z_h)$, respectively, and adding corresponding inequalities gives

$$\begin{aligned} (\widetilde{\eta}_h^j - \eta_h, p_h - p_h^j)_w &\le 0, \\ (\widetilde{\zeta}_h^j - \zeta_h, s_h - s_h^j)_h &\le 0, \\ (\eta_h - \eta_h^j, \nabla(z_h - z_h^j))_w + (\zeta_h - \zeta_h^j, z_h - z_h^j)_h &\le 0. \end{aligned}$$

The rest of the proof of the first estimate is analogous to the proof of [5, Thm. 3.7]. The proof of the monotonicity follows by testing (10) at iterations j and $j+1$ with $(q_h, r_h, w_h) = (p_h^{j+1}, s_h^{j+1}, z_h^{j+1})$ and $(q_h, r_h, w_h) = (p_h^j, s_h^j, z_h^j)$, respectively, and adding the inequalities, which gives

$$\begin{aligned} 0 \le &-(\widetilde{\eta}_h^{j+1} - \widetilde{\eta}_h^j, p_h^j - p_h^{j+1})_w - (\eta_h^j - \eta_h^{j+1}, \nabla(z_h^j - z_h^{j+1}))_w \\ &-(\widetilde{\zeta}_h^{j+1} - \widetilde{\zeta}_h^j, s_h^j - s_h^{j+1})_h - (\zeta_h^j - \zeta_h^{j+1}, z_h^j - z_h^{j+1})_h. \end{aligned}$$

The monotonicity then follows as in the proof of [5, Prop. 3.11]. ∎

In the next step, we show that the residual R_j controls the difference in the objective values.

Lemma 3.1. *Let $(z_h, p_h, s_h; \eta_h, \zeta_h)$ be a saddle-point of L_h^k. Then there exists a constant $C_0 > 0$ such that we have for any $j \ge 1$*

$$\widetilde{\mathscr{E}}(t_k, u_h^k, s_h^j) + \mathscr{R}(s_h^j - z_h^{k-1}) - \widetilde{\mathscr{E}}(t_k, u_h^k, z_h) - \mathscr{R}(z_h - z_h^{k-1}) \le C_0 R_j. \tag{11}$$

Proof. We use the short notation δ_η^j, δ_ζ^j, δ_p^j, δ_s^j and δ_z^j as in Proposition 3.1. Testing (10) with $(q_h, r_h, w_h) = (p_h, s_h, z_h)$, adding the inequalities, noting that $p_h = \nabla z_h$ and $s_h = z_h$ and using $\eta_h^j - \widetilde{\eta}_h^j = \tau_j \nabla(z_h^j - z_h^{j-1})$, $\zeta_h^j - \widetilde{\zeta}_h^j = \tau_j(z_h^j - z_h^{j-1})$ we obtain

$$\begin{aligned} &F(p_h^j) + G(z_h^j) + H(s_h^j) - F(p_h) - G(z_h) - H(s_h) \\ &\leq -(\widetilde{\eta}_h^j, \delta_p^j)_w + (\eta_h^j, \nabla\delta_z^j)_w - (\widetilde{\zeta}_h^j, \delta_s^j)_h + (\zeta_h^j, \delta_z^j)_h \\ &= -(\eta_h^j, d_t\eta_h^j)_w - \tau_j^2(\nabla d_t\delta_z^j, \delta_p^j)_w - (\zeta_h^j, d_t\zeta_h^j)_h - \tau_j^2(d_t\delta_z^j, \delta_s^j)_h. \end{aligned} \tag{12}$$

Testing the optimality conditions of z_h^j and z_h^{j-1} with $w_h = z_h^{j-1}$ and $w_h = z_h^j$, respectively, and adding the corresponding inequalities gives

$$0 \leq -\tau_j^2(d_t\eta_h^j, \nabla d_t z_h^j)_w - \tau_j^2(d_t\zeta_h^j, d_t z_h^j)_h.$$

Using $d_t\eta_h^j = \nabla z_h^j - p_h^j$ and $d_t\zeta_h^j = z_h^j - s_h^j$ and inserting $p_h = \nabla z_h$ and $s_h = z_h$ on the right-hand side gives

$$0 \leq -\tau_j^2(\nabla\delta_z^j, \nabla d_t\delta_z^j)_w + \tau_j^2(\delta_p^j, \nabla d_t\delta_z^j)_w - \tau_j^2(\delta_z^j, d_t\delta_z^j)_h + \tau_j^2(\delta_s^j, d_t\delta_z^j)_h. \tag{13}$$

Adding (12) and (13) we get

$$\begin{aligned} &F(p_h^j) + G(z_h^j) + H(s_h^j) - F(p_h) - G(z_h) - H(s_h) \\ &\leq -(\eta_h^j, d_t\eta_h^j)_w + \tau_j^2(\nabla\delta_z^j, \nabla d_t z_h^j)_w - (\zeta_h^j, d_t\zeta_h^j)_h + \tau_j^2(\delta_z^j, d_t z_h^j)_h \\ &\leq \|\eta_h^j\|_w \|d_t\eta_h^j\|_w + \tau_j^2\|\nabla\delta_z^j\|_w\|\nabla d_t z_h^j\|_w + \|\zeta_h^j\|_h\|d_t\zeta_h^j\|_h + \tau_j^2\|\delta_z^j\|_h\|d_t z_h^j\|_h \leq C_0 R_j, \end{aligned}$$

with C_0 being bounded due to Proposition 3.1.
Let us furthermore note that by Proposition 3.1 we have that s_h^j and z_h^j are bounded, particularly $0 \leq s_h^j \leq z_h^{k-1}$ for all $j \geq 0$. Since f is Lipschitz continuous on bounded intervals, the Hölder inequality, the Lipschitz continuity of f and the inverse estimate $\|w_h\|_{L^\infty(\Omega)} \leq h^{-d/2}\|w_h\|$ (cf. [12, Thm. 4.5.11]) yield

$$\frac{1}{2}\int_\Omega (f(s_h^j) - f(z_h^j))e(u_h^k + g(t_k)) : \mathbb{C}e(u_h^k + g(t_k))\,\mathrm{d}x \leq ch^{-d/2}\|s_h^j - z_h^j\|.$$

We finally observe that using $s_h^j \leq z_h^{k-1}$, $z_h \leq z_h^{k-1}$, the triangle inequality, the inverse estimate $\|\nabla w_h\|_{L^1(\Omega)} \leq ch^{-1}\|w_h\|_{L^1(\Omega)}$ and the equivalence of $\|\cdot\|$ and $\|\cdot\|_h$ we have

$$\begin{aligned}
&\widetilde{\mathscr{E}}(t_k,u_h^k,s_h^j)+\mathscr{R}(s_h^j-z_h^{k-1})-\widetilde{\mathscr{E}}(t_k,u_h^k,z_h)-\mathscr{R}(z_h-z_h^{k-1})\\
&=F(p_h^j)+G(z_h^j)+H(s_h^j)-F(p_h)-G(z_h)-H(s_h)+\kappa\int_\Omega\left(|\nabla s_h^j|-|p_h^j|\right)\mathrm{d}x\\
&\quad+\frac{1}{2}\int_\Omega(f(s_h^j)-f(z_h^j))e(u_h^k+g(t_k)):\mathbb{C}e(u_h^k+g(t_k))\,\mathrm{d}x+\rho\int_\Omega\left(z_h^j-s_h^j\right)\mathrm{d}x\\
&\le C_0R_j+c\kappa h^{-d/2}\|\nabla z_h^j-p_h^j\|_w+c\kappa h^{-1}\|s_h^j-z_h^j\|_h+c(\rho+h^{-d/2})\|z_h^j-s_h^j\|_h\\
&\le C_0R_j.
\end{aligned}$$

which proves the assertion. ■

Remark 3.1. In general, the iterates $(z_h^j)_{j\ge0}$ of Algorithm 3.1 may penetrate the obstacles, i.e., $z_h^j\notin K_k$ for some $j\in\mathbb{N}$, cf. (8). Therefore, if $(z_h^{stop},p_h^{stop},s_h^{stop};\eta_h^{stop},\zeta_h^{stop})$ is the output of the algorithm, we set $z_h^k=s_h^{stop}\in K_k$ to ensure the coercivity of the bulk energy.

3.2 Alternate minimization (5)

In order to solve the full problem (5) we apply the following scheme:

Algorithm 3.2 (Alternate Minimization) *Choose a stable initial pair $(u_h^0,z_h^0)\in\mathscr{S}^1(\mathscr{T}_h)^d\times\mathscr{S}^1(\mathscr{T}_h)$ and a partition $0=t=0<\ldots<t_N=\mathsf{T}$ of the time interval and set $k=1$.*
(1) Compute the unique minimizer u_h^k of

$$u_h\mapsto\widetilde{\mathscr{E}}(t_k,u_h,z_h^{k-1}).$$

(2) Compute an approximate minimizer z_h^k of

$$z_h\mapsto\widetilde{\mathscr{E}}(t_k,u_h,z_h)-\rho(z_h,1)$$

by using Algorithm 3.1, i.e., set $z_h^k=s_h^{stop}$ with s_h^{stop} computed by Algorithm 3.1.
(3) Stop if $k=N$. Otherwise, increase $k\to k+1$ and continue with (1).

The optimality condition for u_h^k in step (1) of the algorithm reads

$$\int_\Omega f(z_h^{k-1})e(u_h^k):\mathbb{C}e(v_h)\,\mathrm{d}x=-\int_\Omega e(g(t_k)):\mathbb{C}e(v_h)\,\mathrm{d}x+\int_{\Gamma_N}u_N(t_k)\cdot v_h\,\mathrm{d}s$$

for all $v_h\in\mathscr{S}^1(\mathscr{T}_h)^d$. In our computation we replace g by $g_h=\mathscr{I}_hg$ on the right-hand side with $\mathscr{I}_h$ being the nodal interpolant and g sufficiently smooth. We further use the midpoint rule to compute for $T\in\mathscr{T}_h$ and $e\in\mathscr{E}_h$ the integrals

$$\int_T f(z_h^{k-1})\,\mathrm{d}x,\quad\text{and}\quad\int_e u_N(t_k)\cdot v_h\,\mathrm{d}s.$$

The computation of u_h^k then amounts to solving a linear system of equations with a weighted stiffness matrix.

4 Existence of semistable energetic solutions for $(\mathbf{U}\times\mathbf{Z},\mathscr{E},\mathscr{R})$

In this section we show that the solutions $(u_{Nh}^k,z_{Nh}^k)_{Nh}$ obtained at each time step t_N^k via the alternate minimization problem (5) can be used to approximate a semistable energetic solution to system $(\mathbf{U}\times\mathbf{Z},\mathscr{E},\mathscr{R})$. To this end, with $\mathscr{S}^1(\mathscr{T}_h)^d$ and $\mathscr{S}^1(\mathscr{T}_h)$ from (7), we set in (5)

$$\mathbf{U}_h := \mathscr{S}^1(\mathscr{T}_h)^d \cap \{v\in C(\overline{\Omega};\mathbb{R}^d), v=0 \text{ on } \Gamma_D\} \text{ and } \mathbf{X}_h := \mathscr{S}^1(\mathscr{T}_h)\,. \tag{14}$$

We recall that $\mathbf{U}_h\subset H^1_D(\Omega;\mathbb{R}^d)$ and $\mathbf{X}_h\subset BV(\Omega)$ for all $h>0$ such that

$$\bigcup_h \mathbf{U}_h \subset H^1_D(\Omega;\mathbb{R}^d) \text{ densely } \text{ and } \bigcup_h \mathbf{X}_h \subset BV(\Omega) \text{ densely }. \tag{15}$$

We now choose a sequence $(h_N)_N$ such that $h_N\to 0$ as $N\to\infty$ and consider a sequence of partitions $(\Pi_N)_N$ of $[0,\mathsf{T}]$ such that the time-step size $\Delta_N\to 0$ as $N\to\infty$. With $\mathscr{E}$ from (4) we introduce the energy functionals $\mathscr{E}_N:[0,\mathsf{T}]\times\mathbf{U}\times\mathbf{Z}\to\mathbb{R}\cup\{\infty\}$,

$$\mathscr{E}_N(t,u,z) := \begin{cases} \mathscr{E}(t,u,z) & \text{if } (u,z)\in \mathbf{U}_{h(N)}\times\mathbf{X}_{h(N)},\\ \infty & \text{otherwise,}\end{cases} \tag{16}$$

where the given data $g(t)$ and $u_{\mathrm{N}}(t)$ are replaced by suitably interpolated versions $g_N(t)$ and $u_{\mathrm{N}N}(t)$ in the discrete spaces, which are uniformly bounded and converge strongly to the original datum. We thus compute for every $N\in\mathbb{N}$ and $h(N)>0$, for each $t_N^k\in\Pi_N$ a solution $(u_N^k,z_N^k)=(u_{Nh(N)}^k,z_{Nh(N)}^k)$ to (5) using Algorithm 3.2. In particular, according to Algorithm 3.1 the pair $(u_N^k,z_N^k)=(u_{Nh}^k,z_{Nh}^k)$ satisfies

$$\forall\, u\in\mathbf{U}_{h(N)}:\ \mathscr{E}_N(t_N^k,u_N^k,z_N^{k-1})\le\mathscr{E}_N(t_N^k,u,z_N^{k-1})\,, \tag{17a}$$

$$\forall\, z\in\mathbf{X}_h:$$

$$\mathscr{E}_N(t_N^k,u_N^k,z_N^k)+\mathscr{R}(z_N^k-z_N^{k-1})\le\mathscr{E}_N(t_N^k,u_N^k,z)+\mathscr{R}(z-z_N^{k-1})+\mathrm{TOL}(N) \tag{17b}$$

with some $h(N)$-dependent tolerance $\mathrm{TOL}(N)$, which bounds the residual R_j^h, cf. Algorithm 3.1, Step (5). In view of Lemma 3.1 a sequence $(\mathrm{TOL}(N))_N$ can be chosen such that

$$\mathrm{TOL}(N)N\to 0 \text{ as } N\to\infty. \tag{18}$$

We evaluate the given data in the partition $\{t_N^0,\dots,t_N^N\}$ which results in an $(N+1)$-tupel. Moreover, for any tupel $(v_N^0,\dots,v_N^N)$ we introduce the piecewise constant left-continuous (right-continuous) interpolant $\overline{v}_N$ ($\underline{v}_N$):

$$\overline{v}_N(t) := v_N^{k+1} \text{ for all } t \in (t_N^k, t_N^{k+1}], \tag{19a}$$

$$\underline{v}_N(t) := v_N^k \text{ for all } t \in [t_N^k, t_N^{k+1}). \tag{19b}$$

Accordingly, $\overline{\mathscr{E}}$, resp. $\underline{\mathscr{E}}$, indicates that the interpolants $\overline{g_N}$ and $\overline{u_{\mathrm{N}N}}$, resp. $\underline{g_N}$ and $\underline{u_{\mathrm{N}N}}$ are used. In particular, thanks to Assumptions 2.1 we have for all $t \in [0, \overline{\mathsf{T}}]$

$$\overline{g}_N(t) \to g(t) \text{ in } \mathbf{U} \ \ \& \ \ \overline{u_{\mathrm{N}N}}(t) \to u_{\mathrm{N}}(t) \text{ in } L^2(\Gamma_{\mathrm{N}}; \mathbb{R}^d). \tag{20}$$

This puts us in the position to find the following properties of the interpolants $(\overline{u}_N, \underline{u}_N, \overline{z}_N, \underline{z}_N)$ constructed from $(u_N^k, z_N^k)_{k=0}^N$ via (19), which we prove in Sec. 4.1:

Proposition 4.1 (Discrete version of (6) **and apriori estimates).** *Let the assumptions of Section 2 hold true and keep $n \in \mathbb{N}$ fixed. For each $k \in \{0, 1, \dots, N\}$ let (u_N^k, z_N^k) satisfy* (17)*. Then the corresponding interpolants $(\overline{u}_N, \underline{u}_N, \overline{z}_N, \underline{z}_N)$ obtained via* (19)*, fulfill the following discrete version of* (6) *for all $t \in [0, \mathsf{T}]$:*

$$\text{for all } \tilde{u} \in \mathbf{U}: \quad \overline{\mathscr{E}}_N(t, \overline{u}_N(t), \underline{z}_N(t)) \le \overline{\mathscr{E}}_N(t, \tilde{u}, \underline{z}_N(t)), \tag{21a}$$

$$\text{for all } \tilde{z} \in \mathbf{X}: \quad \overline{\mathscr{E}}_N(t, \overline{u}_N(t), \overline{z}_N(t)) \le \overline{\mathscr{E}}_N(t, \overline{u}_N(t), \tilde{z}) + \mathscr{R}(\tilde{z} - \overline{z}_N(t)) + \mathrm{TOL}(N), \tag{21b}$$

$$\overline{\mathscr{E}}_N(t, \overline{q}_N(t)) + \mathrm{Diss}_{\mathscr{R}}(\overline{z}_N, [0,t]) \le \overline{\mathscr{E}}_N(0, q_N^0) + \int_0^t \partial_\xi \mathscr{E}_N(\xi, \underline{q}_N(\xi)) \, \mathrm{d}\xi + \mathrm{TOL}(N) N. \tag{21c}$$

In particular, there is a constant $C > 0$ such that the following bounds hold true uniformly for all $N \in \mathbb{N}$:

$$\text{for all } t \in [0, \mathsf{T}]: \ \|u_N(t)\|_{\mathbf{U}} \le C, \tag{22a}$$

$$\text{for all } t \in [0, \mathsf{T}]: \ \|z_N(t)\|_{\mathbf{X}} + \|z_N(t)\|_{L^\infty(\Omega)} \le C, \tag{22b}$$

$$\mathscr{R}(\overline{z}_N(\mathsf{T}) - z_N^0) \le C \ \ \& \ \ \|\overline{z}_N\|_{BV(0,\mathsf{T};\mathbf{Z})} \le C, \tag{22c}$$

where (u_N, z_N) in (22a) *&* (22b) *stands for both $(\overline{u}_N, \overline{z}_N)$ and $(\underline{u}_N, \underline{z}_N)$.*

Based on these properties we will establish the proof of the following convergence result in Sec. 4.2:

Theorem 4.1 (Convergence of $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}_N, \mathscr{R})$ to $(\mathbf{U} \times \mathbf{Z}, \mathscr{E}, \mathscr{R})$ in the sense of (6)**).** *Let the assumptions of Prop. 4.1 hold true. Then there exists a not relabeled subsequence $(\overline{u}_N, \underline{u}_N, \overline{z}_N, \underline{z}_N)_N$ of discrete solutions fulfilling* (21) *&* (22) *for each $N \in \mathbb{N}$ and a limit pair $(u, z) \in \mathrm{B}(0, \mathsf{T}; \mathbf{U}) \times \big(\mathrm{B}(0, \mathsf{T}; \mathbf{X}) \cap BV(0, \mathsf{T}; \mathbf{Z})\big)$ such that the following convergences hold true:*

$$\text{for all } t \in [0, \mathsf{T}]: \ \overline{u}_N(t) \rightharpoonup u(t) \text{ in } \mathbf{U} \text{ and } \overline{z}_N(t) \overset{*}{\rightharpoonup} z(t), \ \underline{z}_N(t) \overset{*}{\rightharpoonup} \underline{z}(t) \text{ in } \mathbf{X}, \tag{23a}$$

$$\text{for all } t \in [0, \mathsf{T}]: \ \underline{z}_N(t) \to z(t) \text{ in } L^p(\Omega) \text{ for all } p \in [1, \infty), \tag{23b}$$

$$\text{for all } t \in [0, \mathsf{T}] \setminus \mathrm{J}: \ \underline{u}_N(t) \rightharpoonup u(t) \text{ in } \mathbf{U} \text{ and } z(t) = \underline{z}(t), \tag{23c}$$

where J *denotes the union of the jump times of* $z, \underline{z} \in BV(0,\mathsf{T};\mathbf{Z})$. *In particular,* (u,z) *is a semistable energetic solution of the system* $(\mathbf{U}\times\mathbf{Z},\mathscr{E},\mathscr{R})$.

4.1 Proof of Prop. 4.1

Proof of properties (21)**:** Taking into account the definition (19) of the interpolants $(\overline{u}_N,\underline{u}_N,\overline{z}_N,\underline{z}_N)$ we see that minimality properties (17) can be directly translated into (21a) & (21b). To find the discrete upper energy-dissipation estimate (21c) we test the minimality of u_N^k in (17a) by u_N^{k-1} and the minimality of z_N^k in (17b) by z_N^{k-1}. This results in

$$\begin{aligned}\mathscr{E}_N(t_N^k,u_N^k,z_N^{k-1}) &\le \mathscr{E}_N(t_N^k,u_N^{k-1},z_N^{k-1})\\ \mathscr{E}_N(t_N^k,u_N^k,z_N^k)+\mathscr{R}(z_N^k-z_N^{k-1}) &\le \mathscr{E}_N(t_N^k,u_N^k,z_N^{k-1})+\mathrm{TOL}(N)\,.\end{aligned}$$

Let now $t\in(0,t_N^n]$ for some $n\le N$. Adding the above two inequalities, adding and subtracting $\mathscr{E}_N(t_N^{k-1},u_N^{k-1},z_N^{k-1})$, and summing over $k\in\{1,\dots,n\}$ we find

$$\begin{aligned}&\mathscr{E}_N(t_N^n,u_N^n,z_N^n)+\mathscr{R}(z_N^n-z_N^0)\\ &\le \mathscr{E}_N(t_N^0,u_N^0,z_N^0)+\sum_{k=1}^n \mathscr{E}_h(t_N^k,u_N^{k-1},z_N^{k-1})-\mathscr{E}_N(t_N^{k-1},u_N^{k-1},z_N^{k-1})+n\mathrm{TOL}(N)\\ &= \mathscr{E}_N(t_N^0,u_N^0,z_N^0)+\sum_{k=1}^n\int_{t_N^{k-1}}^{t_N^k}\partial_\xi\mathscr{E}_N(\xi,u_N^{k-1},z_N^{k-1})\,\mathrm{d}\xi+n\mathrm{TOL}(N)\,,\end{aligned}\tag{24}$$

which yields (21c) for all $t\in(0,t_N^n]$ and integers $n\le N$.

Proof of estimates (22)**:** Observe that there are constants $c_0,c_1>0$, such that for all $(t,u,z)\in[0,\mathsf{T}]\times\mathbf{U}\times\mathbf{Z}$ with $\mathscr{E}_N(t,u,z)<\infty$ it holds $|\partial_t\mathscr{E}_N(t,u,z)|\le c_1(c_0+\mathscr{E}_N(t,u,z))$. This entitles us to apply a Gronwall estimate under the time-integral in (24). Following the classical arguments for energy-dissipation inequalities in the rate-independent setting, cf. e.g. [45, Prop. 2.1.4], results in the estimates

$$c_0+\overline{\mathscr{E}}_N(t_N^k,u_N^k,z_N^k)\le(c_0+\overline{\mathscr{E}}_N(0,u_N^0,z_N^0))\exp(c_1T)\le C\,,\tag{25a}$$

$$\mathscr{R}(z_N^k-z_N^0)\le(c_0+\overline{\mathscr{E}}_N(0,u_N^0,z_N^0))\exp(c_1T)\le C\,,\tag{25b}$$

where the uniform boundedness by $C>0$ is due to (20) and Assumption 2.1. Estimates (22a) are then standardly obtained from the bound (25a), exploiting that $f(0)\ge a>0$ and $\mu>0$ by Assumption 2.1, as well as Korn's and Young's inequality. Estimates (22b) follow from the uniform boundedness of the damage gradients and the fact that $I_{[0,1]}(z_N(t))=0$ a.e. in Ω, ensured by (25a), whereas the first estimate in (22c) is due to (25b) and the second is a direct consrquence taking into account the form of $\mathscr{R}$, see (1a). This concludes the proof of Prop. 4.1. ■

4.2 Proof of Thm. 4.1

Proof of convergences (23)**:** To obtain the convergence result for the damage variables in (23a) we make use of the uniform bound in (22b). This, together with the fact that $\mathscr{R} : \mathbf{Z} \times \mathbf{Z} \to [0,\infty]$ is a weakly sequentially lower semicontinuous dissipation distance, allows us to apply a generalized version of Helly's selection principle, see e.g. [45, Thm. 2.1.24], and hence to find a (not relabeled) subsequence as well as limit functions $z, \underline{z} \in \mathrm{BV}([0,\mathsf{T}],\mathbf{Z})$, such that for all $t \in [0,\mathsf{T}]$:

$$\mathscr{R}(\bar{z}_N(t) - z_N^0) \to \mathscr{R}(z(t) - z_0)\,,\ \bar{z}_N(t) \rightharpoonup z(t) \ \&\ \underline{z}_N(t) \rightharpoonup \underline{z}(t) \ \text{ in } \mathbf{X} \cap L^\infty(\Omega). \quad (26)$$

For some $t \in [0,\mathsf{T}]$ fixed, select a further subsequence such that $\bar{u}_N(t) \rightharpoonup u(t)$ in $\mathbf{U}$. Exploiting the minimality (21a) of $\bar{u}_N(t)$ for $\overline{\mathscr{E}}_N(t,\cdot,\underline{z}_N(t))$ as well as cancellations and the weak sequential lower semicontinuity properties, we find

$$0 \le \limsup_{N\to\infty} \big(\overline{\mathscr{E}}_N(t,\tilde{u},\underline{z}_N(t)) - \overline{\mathscr{E}}_N(t,\bar{u}_N(t),\underline{z}_N(t))\big) \le \mathscr{E}(t,\tilde{u},\underline{z}(t)) - \mathscr{E}(t,u(t),\underline{z}(t))\big) \quad (27)$$

for all $\tilde{u} \in \mathbf{U}$. In other words, $u(t)$ is the unique minimizer of the strictly convex functional $\mathscr{E}(t,\cdot,\underline{z}(t)) : \mathbf{U} \to \mathbb{R} \cup \{\infty\}$. Thus, the above selection of a subsequence of $(\bar{u}_N(t))_N$ was unnecessary. This observation holds for all $t \in [0,\mathsf{T}]$. Moreover, since $\underline{z}$ and and the given data are measurable with respect to time, we also have that $u : [0,\mathsf{T}] \to \mathbf{U}$ is measurable. This concludes the proof of statement (23a).

Convergence result (23b) can now be concluded from (26) using that the weak-star convergence in $BV(\Omega)$ implies strong convergence in $L^1(\Omega)$. In view of the uniform bound in $L^\infty(\Omega)$ the strong $L^1(\Omega)$-convergence can be improved to strong convergence in $L^p(\Omega)$ for any $p \in [1,\infty)$.

Let $\mathrm{J} \subset [0,\mathsf{T}]$ denote the union of the jump times of $z, \underline{z} \in \mathrm{BV}(0,\mathsf{T};\mathbf{Z})$. By the properties of BV-functions, J is at most countable. Consider $t \in [0,\mathsf{T}]\backslash\mathrm{J}$ and a sequence $t_N^{l_N} \to t$ as $N \to \infty$ with $t_N^{l_N} \in \Pi_N$ for all $N \in \mathbb{N}$. With $z_N^{l_N}$ obtained by (5b), it holds that $z_N^{l_N} = \underline{z}_N(t_{l_N}^1) = \bar{z}_k(t_{l_N}^2)$ for all $t_N^{l_N-1} \le t_{l_N}^2 \le t_N^{l_N} \le t_{l_N}^1 \le t_N^{l_N+1}$. For $t_{l_N}^1 \to t$ and $t_{l_N}^2 \to t$ as $N \to \infty$ we thus conclude $z(t) = \underline{z}(t)$ for all $t \in [0,\mathsf{T}]\backslash\mathrm{J}$. Since $u_N^{l_N}$ is the unique minimizer of $\mathscr{E}_N(t_N^{l_N},\cdot,z_N^{l_N-1})$, we find the convergence result for $(\underline{u}_N(t))_N$ in (23c) with similar arguments.

Limit passage in the discrete notion of solution (21)**:** Thanks to convergences (23) and (20) the limit passage in the upper energy-dissipation estimate (21c) can be carried out by means of lower semicontinuity arguments on the left-hand side of (21c). To pass to the limit on the right-hand side of (21c) we make use of the strong convergence $(u_N^0, z_N^0) \to (u_0, z_0)$ in $\mathbf{U} \times \mathbf{X}$ for the energy at initial time and of the fact that $\mathrm{TOL}(N)N \to 0$ as $N \to \infty$. Convergence of the power of the external loadings follows via weak-strong convergence arguments from (23) and (20).

In order to pass to the limit in minimality condition (21a) we have to argue via a suitable recovery sequence. More precisely, for any $\tilde{u} \in \mathbf{U}$ we construct a recovery sequence $(\tilde{u}_N)_N$ such that $u_N \in \mathbf{U}_{h(N)}$ for each $N \in \mathbb{N}$. For this, thanks to the density of smooth functions in $\mathbf{U}$, we first find a sequence $(\hat{u}_N)_N \in C^\infty(\Omega;\mathbb{R}^d) \cap \mathbf{U}$ with

$\|\tilde{u}-\hat{u}_N\|_{\mathbf{U}} \to 0$. We then set

$$\tilde{u}_N := \mathscr{I}_{h(N)}\hat{u}_N\,,$$

which thus ensures that $\tilde{u}_N \to \tilde{u}$ *strongly* in $\mathbf{U}$, cf. [15, Thm. 3.2.3].
Set now $W(e,z) := f(z)\big(\lambda|\operatorname{tr} e(u)|^2 + 2\mu|e(u)|^2\big)$. Observing that, for each $N \in \mathbb{N}$, the term $|\mathrm{D}z_N(t)|(\Omega)$ cancels out in (21a), we find

$$\begin{aligned}
&\int_\Omega f(z(t))\big(\lambda|\operatorname{tr} e(u(t)+g(t))|^2 + 2\mu|e(u(t)+g(t))|^2\big)\,\mathrm{d}x + \int_{\Gamma_{\mathrm{N}}} u_{\mathrm{N}}(t)\cdot(u(t)+g(t))\,\mathrm{d}\mathscr{H}^{d-1}\\
&\le \liminf_{N\to\infty}\Big(\int_\Omega W(e(\overline{u}_N(t)+\overline{g}_N(t)),\underline{z}_N(t))\,\mathrm{d}x + \int_{\Gamma_{\mathrm{N}}} \overline{u_{\mathrm{N}}}(t)\cdot(\overline{u}_N(t)+\overline{g}_N(t))\,\mathrm{d}\mathscr{H}^{d-1}\Big)\\
&\le \lim_{N\to\infty}\Big(\int_\Omega W(e(\tilde{u}_N+\overline{g}_N(t)),\underline{z}_N(t))\,\mathrm{d}x + \int_{\Gamma_{\mathrm{N}}} \overline{u_{\mathrm{N}}}(t)\cdot(\tilde{u}_N+\overline{g}_N(t))\,\mathrm{d}\mathscr{H}^{d-1}\Big)\\
&= \int_\Omega f(z(t))\big(\lambda|\operatorname{tr} e(\tilde{u}+g(t))|^2 + 2\mu|e(\tilde{u}+g(t))|^2\big)\,\mathrm{d}x + \int_{\Gamma_{\mathrm{N}}} u_{\mathrm{N}}(t)\cdot(\tilde{u}+g(t))\,\mathrm{d}\mathscr{H}^{d-1}\,,
\end{aligned}$$

which amounts to (6a) upon adding $|\mathrm{D}z(t)|(\Omega)$ on both sides of the above inequality.
In order to pass to the limit in the semistability inequality (21b) we construct for each $\tilde{z} \in \mathbf{X}$ a *mutual recovery sequence* $(\tilde{z}_N)_N$ such that $\tilde{z}_N \in \mathbf{X}_{h(N)}$ for each $n \in \mathbb{N}$ and such that

$$\begin{aligned}
&\limsup_{N\to\infty}\big(\overline{\mathscr{E}}_N(t,\overline{u}_N(t),\tilde{z}_N) + \mathscr{R}(\tilde{z}_N-\overline{z}_N(t)) - \overline{\mathscr{E}}_N(t,\overline{u}_N(t),\overline{z}_N(t))\big)\\
&\le \mathscr{E}(t,u(t),\tilde{z}) + \mathscr{R}(\tilde{z}-z(t)) - \mathscr{E}(t,u(t),z(t))
\end{aligned}\tag{28}$$

Clearly, since the term on the left-hand side of (28) is nonnegative for all $N \in \mathbb{N}$ a successful limit passage implies the semistability (6b) of the limit.
Consider $\tilde{z} \in \mathbf{X}$ such that $\mathscr{R}(\tilde{z}-z(t)) < \infty$, i.e., such that $\tilde{z} \le z(t)$ a.e. in Ω. Otherwise, (28) can be trivially satisfied for the constant sequence $\tilde{z}_N := \tilde{z}$. In a first step, in order to find an approximant as an element of $\mathbf{X}_{h(N)}$ we proceed as follows: By the density of smooth functions in $BV(\Omega)$ with respect to intermediate (or strict) convergence, we find for given $\tilde{z} \in BV(\Omega)\cap L^p(\Omega)$, $1 \le p < \infty$ a sequence $(z_N^\circ)_N \subset C^\infty(\Omega)\cap BV(\Omega)\cap L^p(\Omega)$ such that $\|\nabla z_N^\circ\|_{L^1(\Omega)} \le |\mathrm{D}\tilde{z}|(\Omega) + \omega(N)$ with $\omega(N) \to 0$ as $N\to\infty$ and $\|\tilde{z}-z_N^\circ\|_{L^p(\Omega)} \to 0$ as $N\to\infty$. Then we set

$$\hat{z}_N := \mathscr{I}_{h(N)}z_N^\circ \in \mathbf{X}_{h(N)} \text{ if } d=2 \text{ and } \hat{z}_N := \mathscr{J}_{h(N)}z_N^\circ \in \mathbf{X}_{h(N)} \text{ if } d=3\,,\tag{29}$$

where $\mathscr{J}_h$ is a quasi-interpolation operator, cf. [16]. This ensures that $\hat{z}_N \to \tilde{z}$ *strongly* in $L^p(\Omega)$ for any $p \in [1,\infty)$ as well as $|\hat{z}_N|(\Omega) \to |\tilde{z}|(\Omega)$ as $N\to\infty$, cf. [3, Thm. 3.1] and [4, Lemma 10.1]. In a second step, we have to modify $\hat{z}_N$ according to the constraint imposed by the unidirectionality of the dissipation potential. More precisely, we apply the construction of the mutual recovery sequence developed in [59, 57], i.e., we define

$$\tilde{z}_N := \max\{0,\min\{\hat{z}_N-\delta_N,\overline{z}_N(t)\}\} \text{ with } \delta_N := \|\overline{z}_N(t)-z(t)\|_{L^2(\Omega)}^{1/2}.\tag{30}$$

We see that this construction satisfies $\mathscr{R}(\tilde{z}_N - \overline{z}_N(t)) < \infty$. In the context of energetic solutions for system $(\mathbf{U}\times\mathbf{Z}, \mathscr{E}, \mathscr{R})$ it was shown that construction (30) satisfies the analogon of the mutual recovery condition (28), in [57, Sec. 2.2] for $\hat{z}_N = \tilde{z} \in BV(\Omega)$ and in [59, Sec. 3.2.5] for $\hat{z}_N = \tilde{z} \in \mathbf{X} = W^{1,r}(\Omega)$ with $r \in (1,\infty)$. Moreover, in a thermo-viscoelastic setting, [51, Sec. 4.2] handles the limit passage in the semistability inequality from an adhesive delamination model with a regularization of Modica-Mortola-type to a delamination model, where the delamination variable is the characteristic function of a set of finite perimeter and thus only accounts for the sound and the broken state of the glue. Many of the arguments developed in the context of [59, 57, 51] can be used also in the present situation. In particular, as in [59, Sec. 3.2.5] we introduce the sets

$$A_N := [\hat{z}_N - \delta_N \geq \overline{z}_N(t)]\ B_N := [0 \leq \hat{z}_N - \delta_N \geq \overline{z}_N(t)] \text{ and } C_N := \Omega\backslash(A_N \cup B_N)\,, \tag{31}$$

where we used the short-hand $[\ldots] := \{x \in \Omega \text{ s.th. } \ldots\}$. Exploiting the convergence (23b) it can be shown as in [59, Sec. 3.2.5] that

$$\mathscr{L}^d(B_N) = \mathscr{L}^d(\Omega\backslash(A_N \cup C_N)) \to 0\,. \tag{32}$$

It can also be argued that $\tilde{z}_N \in \mathbf{X}_{N(h)}$ for $\hat{z}_N, \overline{z}_N(t) \in \mathbf{X}_{h(N)}$ and $\|\tilde{z}_N\|_{W^{1,1}(\Omega)} \leq \|\hat{z}_N\|_{W^{1,1}(\Omega)} + \|\overline{z}_N(t)\|_{W^{1,1}(\Omega)} \leq C$. This implies that $\tilde{z}_N \overset{*}{\rightharpoonup} w$ in $BV(\Omega)$ as well as $\tilde{z}_N \to w$ in $L^1(\Omega)$. By Riesz' convergence theorem once then can extract a (not relabeled) subsequence $\tilde{z}_N \to w$ converging pointwise a.e. in Ω and due to construction (30) combined with (32) we conclude that $w = \tilde{z}$.
In order to verify (28) we now observe that

$$\begin{aligned}
&\limsup_{N\to\infty} \big(\overline{\mathscr{E}}_N(t, \overline{u}_N(t), \tilde{z}_N) + \mathscr{R}(\tilde{z}_N - \overline{z}_N(t)) - \overline{\mathscr{E}}_N(t, \overline{u}_N(t), \overline{z}_N(t))\big) \\
&\leq \limsup_{N\to\infty} \tfrac{1}{2} \int_\Omega (f(\tilde{z}_N) - f(\overline{z}_N(t)))\big(\lambda\,|\operatorname{tr} e(\overline{u}_N + \overline{g}_N(t))|^2 + 2\mu |e(\overline{u}_N + \overline{g}_N(t)|^2\big)\,\mathrm{d}x \\
&\quad + \limsup_{N\to\infty} \big(\|\nabla\tilde{z}_N\|_{L^1(\Omega)} - \|\nabla\overline{z}_N(t)\|_{L^1(\Omega)}\big) + \limsup_{N\to\infty} \mathscr{R}(\tilde{z}_N - \overline{z}_N(t))\,,
\end{aligned}$$

where we used that the energy terms involving the Neumann boundary condition cancel out. Since $\tilde{z} \leq z(t)$ by assumption and $\tilde{z}_N \leq z_N(t)$ by construction, we observe that $(f(z) - f(z(t))), (f(\tilde{z}_N) - f(z_N(t))) \leq 0$. Hence we can pass to the limit in the quadratic bulk term via weak lower semicontinuity, exploiting convergences (23) and (20). Furthermore, we have that $\mathscr{R}(\tilde{z}_N - \overline{z}_N(t)) \to \mathscr{R}(\tilde{z} - z(t))$ thanks to convergence (23b) and the properties of construction (30). It remains to handle the difference of the damage gradients. In view of (30) & (31) we see that

$$\begin{aligned}
\|\nabla\tilde{z}_N\|_{L^1(\Omega)} - \|\nabla\overline{z}_N(t)\|_{L^1(\Omega)} &\leq \|\nabla\hat{z}_N\|_{L^1(A_N)} - \|\nabla\overline{z}_N(t)\|_{L^1(B_N\cup C_N)} \\
&\leq \|\nabla\hat{z}_N\|_{L^1(\Omega)} - \|\nabla\overline{z}_N(t)\|_{L^1(B_N\cup C_N)}\,,
\end{aligned}$$

where $\|\nabla\hat{z}_N\|_{L^1(\Omega)} \to |\mathrm{D}\tilde{z}|(\Omega)$ by construction. Using that $\|\nabla\overline{z}_N(t)\|_{L^1(B_N\cup C_N)} = |\mathrm{D}\overline{z}_N(t)|\,|_{B_N\cup C_N}\,(\Omega)$, i.e., the variation of $\overline{z}_N(t)$ in Ω restricted to the set $B_N \cup C_N$,

we may conclude the proof by repeating the weak lower semicontinuity arguments developed in [57, Sec. 2.2] to find that

$$-\liminf_{N\to\infty} \|\nabla \bar{z}_N(t)\|_{L^1(B_N\cup C_N)} \leq -|\mathrm{D}z(t)|(\Omega)\,.$$

This concludes the proof of (28) and of Thm. 4.1. ■

5 Numerical Experiments

We report in this section the numerical results for two two-dimensional benchmark problems taken from [1] and [41].

5.1 Membrane with hole

In the sequel we specify all relevant information for the first benchmark problem from [1].

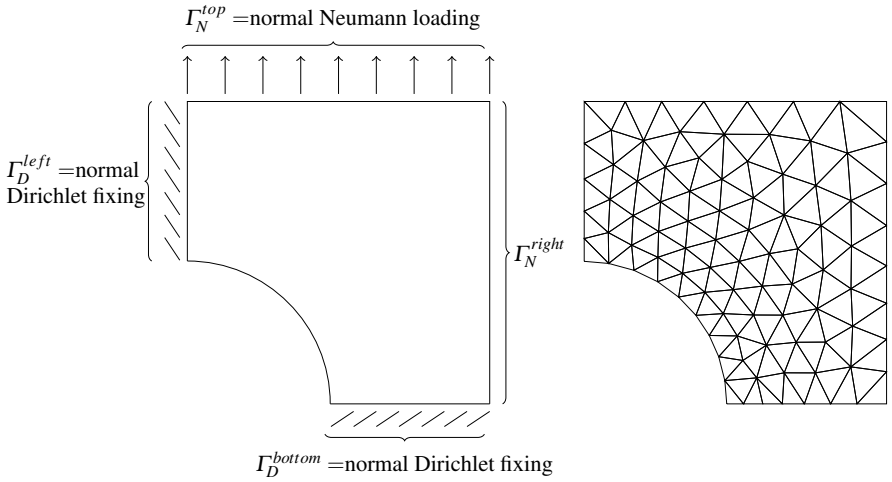

Fig. 1: Left: Domain Ω and illustration of applied traction for membrane with hole: the material is pulled from above. Right: Coarse triangulation ($h_{\min} = 0.055$).

Problem specification:
We consider a body occupying a square domain with a hole around the center and which is pulled from above and below. Due to symmetry we regard only the upper

right quarter of the domain. We summarize all relevant information for the first example in the following.

- **Geometry:** Length scale $L = 1$ mm;
  Domain $\Omega = (0,L)^2 \setminus \{x \in \mathbb{R}^2 : \ |x| \leq L\sqrt{2}/3\}$;
  Dirichlet boundary $\Gamma_D = ([L\sqrt{2}/3, L] \times \{0\}) \cup (\{0\} \times [L\sqrt{2}/3, L])$
- **Time horizon:** $\mathsf{T} = 1$ s
- **Load:** Dirichlet data:

$$u_D(t,x)_1 = 0 \,\text{mm/s} \quad \text{if } x \in \Gamma_D^{left},$$
$$u_D(t,x)_2 = 0 \,\text{mm/s} \quad \text{if } x \in \Gamma_D^{bottom};$$

  Neumann data:

$$u_N(t,x) = \begin{bmatrix} 0 \, \frac{\text{N}}{\text{mm}^2\text{s}} \\ t \cdot 1 \, \frac{\text{N}}{\text{mm}^2\text{s}} \end{bmatrix} \qquad \text{if } x \in \Gamma_N^{top},$$
$$u_N(t,x) = \begin{bmatrix} 0 \, \frac{\text{N}}{\text{mm}^2\text{s}} \\ 0 \, \frac{\text{N}}{\text{mm}^2\text{s}} \end{bmatrix} \qquad \text{if } x \in \Gamma_N^{right};$$

  The geometry and the applied traction are illustrated in Fig. 1.
- **Material parameters:** Young's modulus $E = 2900 \,\text{N/mm}^2$;
  Poisson's ratio $\nu = 0.4$;
  Lamé constants

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)} \approx 4142.9 \, \frac{\text{N}}{\text{mm}^2}, \ \mu = \frac{E}{2(1+\nu)} \approx 1035.7 \, \frac{\text{N}}{\text{mm}^2};$$

  The function f is chosen as $f(z) = a + (b-a)z$ with $a = 1/2$, $b = 1$;
  Damage toughness $\rho = 4 \cdot 10^{-4} \,\text{N/mm}^2$;
  Regularization factor $\kappa = 10^{-6} \,\text{N/mm}^2$
- **Initialization:** Initial stable state $u_h^0 \equiv 0$, $z_h^0 \equiv 1$.
- **Discretization:** Four triangulations $\mathscr{T}_h$ generated with `distmesh` (see [48]) with mesh sizes (in mm)

$$h \approx 0.204, \ h_{\min} \approx 0.055; \quad h \approx 0.09, \ h_{\min} \approx 0.034;$$
$$h \approx 0.054, \ h_{\min} \approx 0.016; \quad h \approx 0.029, \ h_{\min} \approx 0.008;$$

  Equidistant partition of $[0, \mathsf{T}]$ with $\Delta t = 10/(\lceil \mathsf{T}/h_{\min}^2 \rceil)$
- **Algorithm:** Algorithm 3.1 stops if $R_j \leq 10^{-6}/(2\max\{1, 1/(\tau_j h_{\min})\})$;
  $\overline{\tau} = h_{\min}^{-2}$, $\underline{\tau} = 10^{-4}$, $\delta = 0.5$, $\underline{\gamma} = 0.5$, $\overline{\gamma} = 0.999$

Aim:

Since we are dealing with a BV-regularized damage model, i.e., the damage variable is allowed to jump in space, we want to investigate if the interfaces between damaged and undamaged parts of the material are sharp at least on the scale h of the mesh resolution. We will also compare the results with an H^1-regularization, i.e., we replace $\kappa|Dz|(\Omega)$ by $\kappa\|\nabla z\|^2$ and by $\kappa h_{\min}\|\nabla z\|^2$ in order to investigate the influence of the chosen regularization term on the damage evolution. The dependence of the solutions on the mesh size will also be analyzed.

Results:

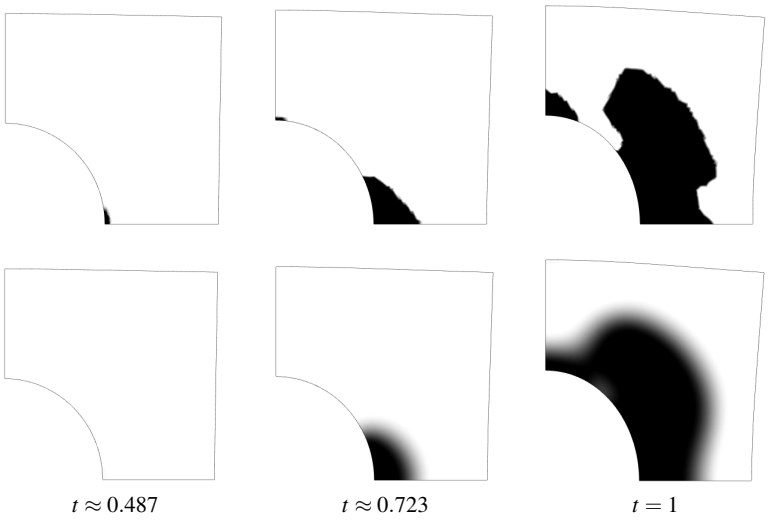

Fig. 2: Damage evolution with mesh size $h_{\min} \approx 0.008$ and time step size $\Delta t = 1/1492$. Top: BV-regularization. Bottom: Unweighted H^1-regularization. Displacements are magnified by factor 40.

In Fig. 2 three time steps of the damage evolution computed by Algorithm 3.2 for $h_{\min} = 0.008$ are depicted, both for the damage model with BV-regularization and unweighted H^1-regularization of the damage variable. The displacements are magnified by a factor of 40. One can clearly observe that the BV-regularization leads to sharp jumps (on the scale of h) while the transitions from undamaged ($z = 1$) to damaged ($z = 0$) parts of the material are smeared out for the H^1-regularization as it could be expected. The evolutions are more similar to each other if the H^1 regularization term is scaled with the factor $h_{\min}$ as it can be seen from Fig. 3. However, it is not clear whether the regularization term $\kappa h_{\min}\|\nabla z\|^2$ can be analytically justified, particularly with respect to the limit $h \to 0$.
In Fig. 4 we verify the energy estimate (21c) as a function of t_N^n, $n \leq N$, for three mesh sizes $h_{\min} = 0.055, 0.016, 0.008$. Obviously, the energy inequality holds and

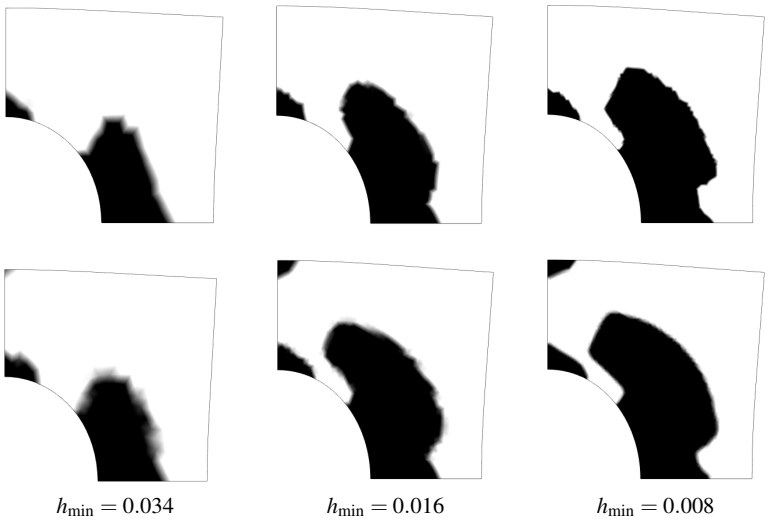

Fig. 3: Damage at $t = 1$ for different mesh sizes and time step sizes. Top: BV-regularization. Bottom: Weighted H^1-regularization with $\kappa h_{\min}\|\nabla z\|^2$. Displacements are magnified by factor 40.

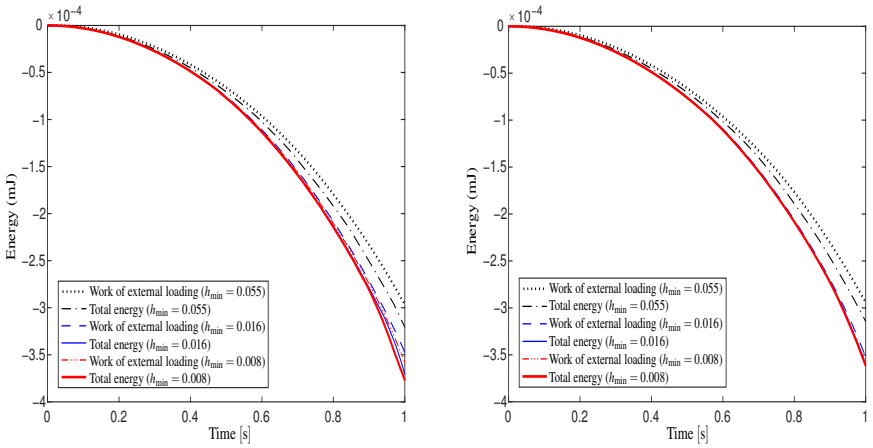

Fig. 4: Verification of energy estimate (21c) as a function of t_N^n for three different mesh sizes. Sum of stored and dissipated energy (= total energy = left-hand side of (21c)); work of external loading up to time t_N^n (= right-hand side of (21c) with $\overline{\mathscr{E}}_N(0, q_N^0) = 0$). Left: with BV-regularization; right: with H^1-regularization.

is increasing in time which is in accordance to (21c) since the inequality holds for all $t_N^k < t_N^n$, $1 \le k \le n \le N$.

5.2 Notched square

The relevant information for the second test, which is taken from [41], are given below.

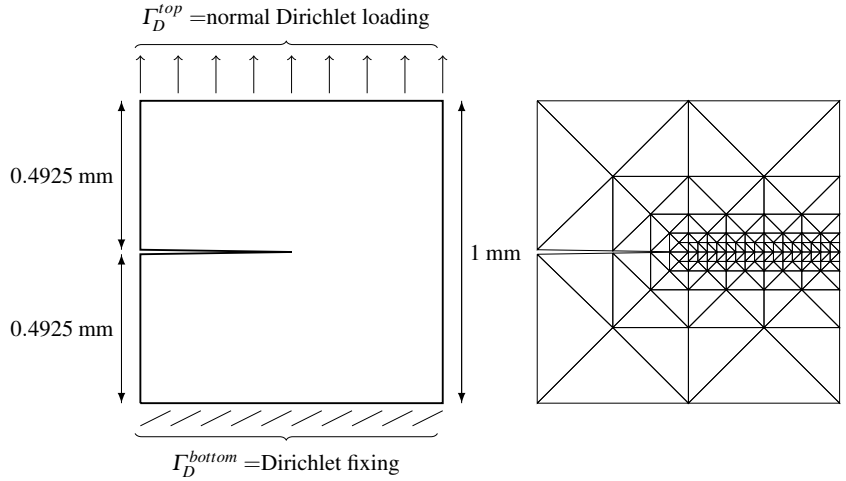

Fig. 5: Left: Domain Ω and illustration of boundary conditions for notched square: the material is pulled from above. Right: Initial locally refined mesh.

Problem specification:
We consider a body occupying a square domain with a notch reaching from the middle of the left edge to the center of the specimen. The specimen is pulled from above and clamped at the bottom. We summarize all relevant information for this example in the following.

- **Geometry:** Length scale $L = 1$ mm;
  Domain $\Omega = (0,L)^2 \setminus \mathrm{conv}\{(0,0.5075),(0.5,0.5),(0,0.4925)\}$;
  Dirichlet boundary $\Gamma_D = ([0,L]\times\{0\}) \cup ([0,L]\times\{L\})$
- **Time horizon:** $\mathsf{T} = 1$ s
- **Load:** Dirichlet data:

$$u_D(t,x)_2 = t \cdot 0.002 \text{ mm/s} \qquad \text{if } x \in \Gamma_D^{top},$$
$$u_D(t,x) = \begin{bmatrix} 0 \text{ mm/s} \\ 0 \text{ mm/s} \end{bmatrix} \qquad \text{if } x \in \Gamma_D^{bottom};$$

Neumann data:

$$u_N(t,x) = \begin{bmatrix} 0 \frac{\text{N}}{\text{mm}^2\text{s}} \\ 0 \frac{\text{N}}{\text{mm}^2\text{s}} \end{bmatrix} \qquad \text{if } x \in \Gamma_N;$$

The geometry is illustrated in Fig. 5.

- **Material parameters:** Young's modulus $E = 210 \text{ kN/mm}^2$;
  Poisson's ratio $\nu = 0.3$;
  Lamé constants

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)} \approx 121.15 \frac{\text{kN}}{\text{mm}^2}, \ \mu = \frac{E}{2(1+\nu)} \approx 80.77 \frac{\text{kN}}{\text{mm}^2};$$

  The function f is chosen as $f(z) = a + (b-a)z$ with $a = 10^{-6}$, $b = 1$;
  Damage toughness $\rho = 2.7 \cdot 10^{-3} \text{ kN/mm}^2$;
  Regularization factor $\kappa = 10^{-7} \text{ kN/mm}^2$
- **Initialization:** Initial stable state $u_h^0 \equiv 0$, $z_h^0 \equiv 1$.
- **Discretization:** Three triangulations $\mathscr{T}_h$ generated by uniform refinement of an initial mesh refined locally in region of expected damage evolution with mesh sizes (in mm)

$h \approx 0.25$, $h_{\min} \approx 0.0156$; $h \approx 0.125$, $h_{\min} \approx 0.0078$; $h \approx 0.0625$, $h_{\min} \approx 0.0039$;

  Equidistant partition of $[0, \mathsf{T}]$ with $\Delta t = 10/(\lceil \mathsf{T}/h_{\min}^2 \rceil)$
- **Algorithm:** Algorithm 3.1 stops if $R_j \leq 10^{-7}/(2\max\{1, 1/(\tau_j h_{\min})\})$;
  $\overline{\tau} = h_{\min}^{-2}$, $\underline{\tau} = 10^{-3}$, $\delta = 0.5$, $\underline{\gamma} = 0.5$, $\overline{\gamma} = 0.999$

Aim:
The aim of this experiment is to compare the resulting damage evolution with established numerical experiments for damage or crack propagation reported in [41, 61], which are based on a phase field approach, and to check whether our damage model yields qualitatively the same results.

Results:
In Fig. 6 and 7 three snapshots of the damage evolution computed by Algorithm 3.2 for $h_{\min} \approx 0.0078$ are depicted for the damage model with BV-regularization and H^1-regularization, respectively, of the damage variable. Let us remark that the damage evolution observed in Fig. 6 qualitatively matches with the evolution reported in [41, Fig. 8] and [61, Fig. 4], i.e., the damage concentrates in a thin region around the horizontal line connecting the tip of the notch and the boundary on the

right. Moreover, in contrast to the models discussed in [41, 61] the model presented in this paper is a damage model without phase field character and models by $a > 0$ only partial damage. Particularly, our model is not of Ambrosio-Tortorelli type.
In Fig. 8 the energy curves corresponding to (21c) as a function of t_N^n are depicted for three different mesh sizes . One can again observe that the energy inequality holds and that the gap is increasing in time. Furthermore, one can observe in Fig. 8 that the damage evolves relatively fast to the right boundary after the damage process has been initiated, e.g., for $h_{\min} = 0.0039$ it takes only a few milliseconds from initiation of the damage until damage reaches the boundary which is also in accordance with the observations made in [41, 61]. Note that the damage is triggered earlier for smaller mesh sizes which is on the one hand due to the singularity of the stress at the crack tip and on the other hand due to the finer partition of the time interval for smaller mesh sizes. This underlines the need for proper adaptive refinement techniques both for the space and the time variable.

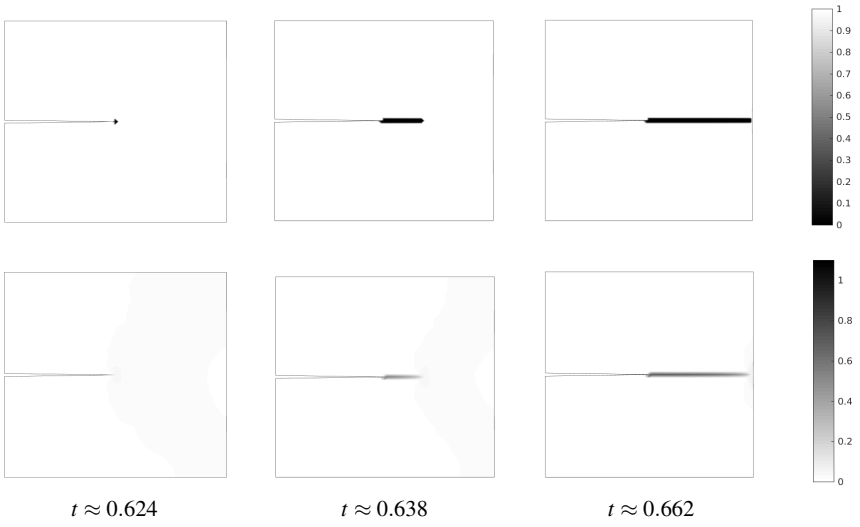

Fig. 6: BV-regularized evolution for notched square with mesh size $h_{\min} \approx 0.0078$ and time step size $\Delta t = 1/1638$. Top: Evolution of damage variable z. Bottom: Stress $\sqrt{f(z)e(u+g(t)) : \mathbb{C}e(u+g(t))}$.

6 Conclusion

The numerical experiments show that our damage model can qualitatively capture the important features of damage evolution or crack propagation already reported in [41, 61, 10] for a phase field approach and, e.g., in [47, 54, 53] for similar numerical

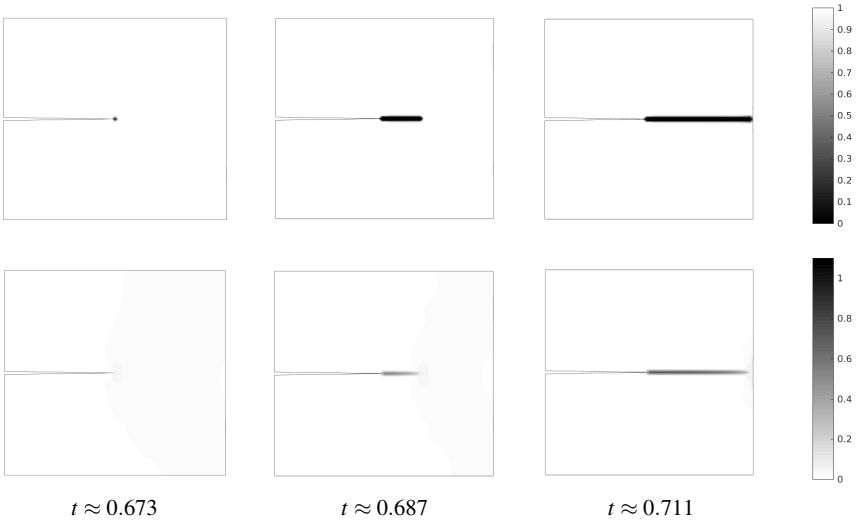

Fig. 7: H^1-regularized evolution for notched square with mesh size $h_{\min} \approx 0.0078$ and time step size $\Delta t = 1/1638$. Top: Evolution of damage variable z. Bottom: Stress $\sqrt{f(z)e(u+g(t)) : \mathbb{C}e(u+g(t))}$.

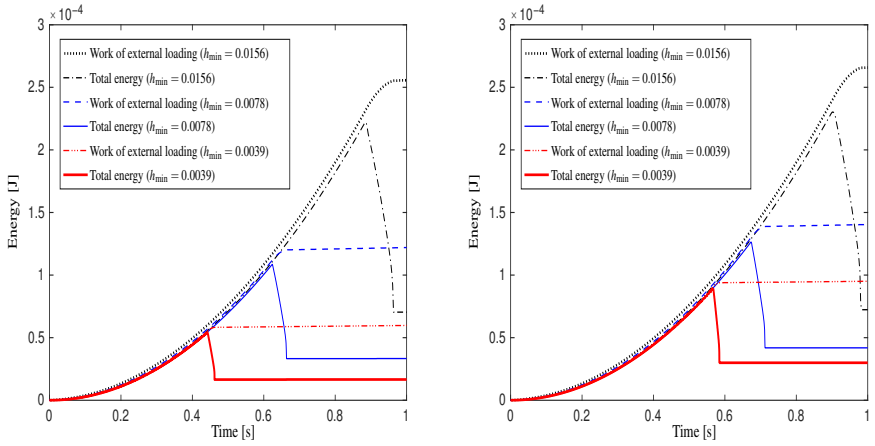

Fig. 8: Verification of energy estimate (21c) as a function of t_N^n for three different mesh sizes. Sum of stored and dissipated energy (= total energy = left-hand side of (21c)); work of external loading up to time t_N^n (= right-hand side of (21c) with $\overline{\mathscr{E}}_N(0, q_N^0) = 0$). Left: with BV-regularization; right: with H^1-regularization.

experiments based on energetic formulations. Depending on the particular setting the BV-regularization of the damage variable can lead to transitions from damaged to undamaged zones in the material that are significantly sharper than for an H^1-regularization as it has been observed in our first experiment.

Acknowledgments

The authors acknowledge financial support for the project "Finite element approximation of functions of bounded variation and application to model of damage, fracture and plasticity" (BA 2268/2-1) by the DFG via the priority program "Reliable Simulation Techniques in Solid Mechanics, Development of Non-standard Discretization Methods, Mechanical and Mathematical Analysis" (SPP 1748).
