

DISCRETE TOTAL VARIATION FLOWS WITHOUT REGULARIZATION*

SÖREN BARTELS[†], RICARDO H. NOCHETTO[‡], AND ABNER J. SALGADO[§]

Abstract. We propose and analyze an algorithm for the solution of the L^2 -subgradient flow of the total variation functional. The algorithm involves no regularization, thus the numerical solution preserves the main features that motivate practitioners to consider this type of energy. We propose an iterative scheme for the solution of the arising problems, show that the iterations converge, and develop a stopping criterion for them. We present numerical experiments which illustrate the power of the method, explore the solution behavior, and compare with regularized flows.

Key words. Total Variation; Singular Diffusion; Maximal Monotone Operators; Subgradient flows; Variational Inequalities.

1. Introduction. This work is concerned with the approximation of solutions to the following (formal) initial boundary value problem:

$$\begin{cases} u_t = \nabla \cdot \left(\frac{\nabla u}{|\nabla u|} \right), & \text{in } \Omega \times (0, T), \\ \frac{\nabla u}{|\nabla u|} \cdot \mathbf{n} = 0, \text{ on } \partial\Omega, \quad u|_{t=0} = u_0, & \text{in } \Omega. \end{cases} \quad (1.1)$$

Here Ω is an open, bounded and connected subset of \mathbb{R}^d with $d \geq 1$; $\partial\Omega$ denotes the boundary of Ω and \mathbf{n} its exterior unit normal; and $T > 0$ is a positive and finite time. This equation and related ones are commonly known as *very singular diffusion equations* (see [26, 27]) since in flat regions, i.e., $|\nabla u| = 0$, the diffusion is so strong that it is not a local effect anymore.

Beginning with the seminal paper [34] equations of this class have received considerable attention from the image processing community, since such models preserve discontinuities while removing noise and other artifacts (see also [11, 13, 16, 17, 31]). In addition, such equations appear in the modeling of grain boundary motion [29]; facet formation and evolution [23]; electromigration [25] and various other problems stemming from materials science. This clearly shows that the development of efficient and accurate numerical schemes for the solution of this class of problems is of extreme importance. To the best of our knowledge however, the techniques advocated in the literature for the solution of these equations as a rule involve a regularization somewhat related with replacing the singular term by

$$|\nabla u|_\epsilon = \sqrt{\epsilon^2 + |\nabla u|^2}, \quad \epsilon > 0; \quad (1.2)$$

see, for instance, [9, 19, 21, 22, 30]. The disadvantages of this approach are twofold: first, although these methods have been shown to converge, there is no clear understanding of the relation between the regularization parameter ϵ and the discretization

parameters; second, the regularization destroys certain fundamental features of the solutions which motivate the introduction of such models in the first place.

A notable exception to the trend mentioned above is the work [7] which, inspired by the ideas advanced in [12], develops a finite element scheme for total variation minimization which involves no regularization. In this work we adapt and extend the ideas presented in [7] to the study of total variation flows. We propose and analyze an unconditionally stable and convergent discretization scheme for the approximation of (1.1). In addition, we study an iterative scheme for the solution of the discrete problems and develop an *a posteriori* error estimator that provides a robust stopping criterion for the iterative scheme that guarantees that, although we only have approximate solutions, the convergence properties of the method are not affected.

This work is organized as follows. The notation and conventions are set in Section 2. In §2.1 we recall the definition and main properties of functions of bounded variation and, in addition, we present an approximation result for these functions. This will be our workhorse during the derivation of error estimates. The proper framework to understand (1.1), i.e., total variation flow and its properties are described in Section 3. Time and space discretization are discussed in Section 4, where we begin by reviewing results on implicit semidiscretizations of gradient flows in Hilbert spaces. Then we provide a general theory for fully discrete subgradient flows in Hilbert spaces, which we later apply to our problem. One of the salient novelties of this general theory is that we allow for modifications in the energy which can be used, for instance, to take into account the effects of quadrature. In Section 5 we propose an iterative scheme for the solution of the fully discrete problems, and devise a stopping criterion for the iterations, which guarantees that the convergence orders are not damaged. Section 6 contains a series of numerical experiments, which illustrate and extend the properties and theory for the developed scheme. Finally, in Section 7, we apply the approximation result of §2.1 to the problem of total variation minimization and prove convergence estimates similar to those available in the literature, but with reduced regularity assumptions.

2. Notation and Preliminaries. We denote by Ω a bounded domain in \mathbb{R}^d with $d \geq 1$. The boundary of Ω is denoted by $\partial\Omega$ and we assume that $\partial\Omega \in \mathcal{C}^{0,1}$. We set $T > 0$ to be a finite final time. As usual, we denote by $L^p(\Omega)$ the space of Lebesgue integrable functions with exponent $p \in [1, \infty]$ and by $W_p^s(\Omega)$, $s \in \mathbb{R}$, the usual Sobolev spaces. Spaces of vector valued functions and their elements will be represented with boldface characters. Recall that the following interpolation inequality holds (cf. [24])

$$\|w\|_{L^r} \leq \|w\|_{L^p}^s \|w\|_{L^q}^{1-s}, \quad p, q \in [1, \infty], \quad \frac{1}{r} = \frac{s}{p} + \frac{1-s}{q}, \quad s \in [0, 1]. \quad (2.1)$$

Whenever E is a normed space, we denote its norm by $\|\cdot\|_E$ and its dual by E' . The L^2 -inner product will be denoted by $\langle \cdot, \cdot \rangle$. Function spaces of vector-valued functions will be denoted by boldface characters. For function spaces, if it is clear from the context, we will omit the domain of definition. We denote by $\mathfrak{B}_1(E)$ the unit ball in E , i.e., the set $\mathfrak{B}_1(E) = \{x \in E : \|x\|_E \leq 1\}$. Let $\phi : [0, T] \rightarrow E$ be a measurable function in the Bochner sense, then, for $p \in [1, \infty]$, we define

$$\|\phi\|_{L^p(E)}^p = \int_0^T \|\phi(t)\|_E^p dt, \quad p < \infty, \quad \|\phi\|_{L^\infty(E)} = \operatorname{ess\,sup}_{t \in [0, T]} \|\phi(t)\|_E.$$

We will denote by $\frac{d\phi}{dt}$ the time derivative of ϕ .

To deal with time discretization, we introduce a time-step $\Delta t > 0$, for simplicity assumed constant. Then we partition the time interval via $t^k = k\Delta t$ with $k = \overline{0, K}$ and $K = \lceil T/\Delta t \rceil$. We use the notation $\phi^{\Delta t} = \{\phi^k\}_{k=0}^K$, introduce the time increment operator

$$\delta\phi^k = \phi^k - \phi^{k-1}, \quad (2.2)$$

and the extrapolation operator

$$\phi^{*,k+1} = \phi^0, \quad k = 0, \quad \phi^{*,k+1} = \phi^k + \delta\phi^k, \quad k > 0. \quad (2.3)$$

For $\phi^{\Delta t} \subset E$ and $p \in [1, \infty]$, we introduce the (semi)norms

$$\|\phi^{\Delta t}\|_{\ell^p(E)}^p = \Delta t \sum_{k=0}^K \|\phi^k\|_E^p, \quad \|\phi^{\Delta t}\|_{\mathfrak{h}^{1/2}(E)}^2 = \sum_{k=1}^K \|\delta\phi^k\|_E^2,$$

with the usual modification for $p = \infty$. Given a sequence $\phi^{\Delta t} \subset E$ we will want to be able to compare it to functions defined on $[0, T]$. To this end, we define the Rothe interpolant $\widehat{\phi}$, that is, the piecewise linear function

$$\widehat{\phi}(t) = \frac{t - t^k}{\Delta t} \phi^{k+1} + \frac{t^{k+1} - t}{\Delta t} \phi^k, \quad t \in [t^k, t^{k+1}]. \quad (2.4)$$

Notice that, by construction, $\widehat{\phi} \in \mathcal{C}^{0,1}(E)$, and $\|\widehat{\phi}\|_{L^\infty(E)} = \|\phi^{\Delta t}\|_{\ell^\infty(E)}$. Recall also the well-known summation by parts formula: for every $\phi^{\Delta t}, \psi^{\Delta t} \subset L^2(\Omega)$,

$$\sum_{k=0}^{K-1} (\langle \phi^k, \delta\psi^{k+1} \rangle + \langle \delta\phi^{k+1}, \psi^{k+1} \rangle) = \langle \phi^K, \psi^K \rangle - \langle \phi^0, \psi^0 \rangle. \quad (2.5)$$

We will carry out the space discretization with finite element techniques. In other words, given Ω we introduce a so-called triangulation $\mathcal{T}_h = \{T\}$ as a collection of cells that satisfy the usual conformity and shape regularity assumptions [14, 20], and are such that $\bar{\Omega} = \bigcup_{T \in \mathcal{T}_h} \bar{T}$. We parametrize our collection of triangulations via $h = \max\{\text{diam}(T) : T \in \mathcal{T}_h\}$. For simplicity, we assume that each T is the isoparametric image of a so-called reference cell, which can be either $\widehat{T} = [-1, 1]^d$, in which case we call the cells cubic; or $\widehat{T} = \{(x_1, \dots, x_d) \in \mathbb{R}^d : x_i \geq 0, \sum_{i=1}^d x_i \leq 1\}$, which are called simplices. We denote by $\{z_{j,T}\}$ the vertices of the cell T and set $\mathcal{N}_T = \#\{z_{j,T}\}$. Clearly, $\mathcal{N}_T = 2^d$ for cubes and $\mathcal{N}_T = d + 1$ for simplices.

We define the finite element space

$$\mathbb{V}_h = \{w_h \in \mathcal{C}^0(\bar{\Omega}) : v_h|_T \in \mathcal{P}\} \subset W_\infty^1(\Omega), \quad (2.6)$$

where $\mathcal{P} = \mathbb{Q}_1$ for cubes and $\mathcal{P} = \mathbb{P}_1$ for simplices. Here \mathbb{Q}_1 denotes the space of polynomials of degree at most one in each variable and \mathbb{P}_1 the space of polynomials of total degree not greater than one.

For a function w such that $w|_T \in \mathcal{C}^0(\bar{T})$, we define its local Lagrange interpolant $\mathcal{I}_h w$ by

$$\mathcal{I}_h w|_T \in \mathcal{P} : \mathcal{I}_h w|_T(z_{j,T}) = w|_T(z_{j,T}), \quad j = \overline{1, \mathcal{N}_T}, \quad \forall T \in \mathcal{T}_h. \quad (2.7)$$

This operator satisfies

$$\|w - \mathcal{I}_h w\|_{L^p(T)} + h\|\nabla(w - \mathcal{I}_h w)\|_{L^p(T)} \leq ch^2\|D^2 w\|_{L^p(T)}, \quad (2.8)$$

see, e.g. [14], for a proof. We remark also that if $w \in \mathcal{C}^0(\bar{\Omega})$, then $\mathcal{I}_h w \in \mathbb{V}_h$. It will be also necessary to introduce the Clément interpolant (cf. [15]) $\Pi_h : L^1(\Omega) \rightarrow \mathbb{V}_h$. This operator enjoys approximation properties similar to (2.8), the only difference being that the domain on the right hand side is a neighborhood of T . More importantly, the operator is stable under any Sobolev norm, i.e.,

$$\|\Pi_h w\|_{W_p^s} \leq c\|w\|_{W_p^s}, \quad s \geq 0, \quad p \in [1, \infty]. \quad (2.9)$$

We will denote by c a constant whose value might change at each occurrence.

2.1. Functions of Bounded Variation and their Approximation. We say that a function $w \in L^1(\Omega)$ belongs to the space $BV(\Omega)$ (is of bounded variation) if its derivative, Dw , in the sense of distributions is a Radon measure. In other words, $|Dw|(\Omega) < \infty$, where for any Borel set $A \subset \Omega$,

$$|Dw|(A) = \sup \left\{ \int_A w \nabla \cdot \mathbf{q} : \mathbf{q} \in \mathcal{C}_0^\infty(A), \|\mathbf{q}\|_{\mathbf{L}^\infty(A)} \leq 1 \right\}.$$

The space $BV(\Omega)$ endowed with the norm $\|w\|_{BV} = \|w\|_{L^1} + |Dw|(\Omega)$ is a Banach space. For more details on this space, we refer to [1, 38]. Let us present a result on approximation by smooth functions, in the case of a star-shaped domain.

PROPOSITION 2.1 (Approximation of BV functions). *Assume that Ω is bounded, star-shaped with respect to a point and $\partial\Omega \in \mathcal{C}^{0,1}$. If $w \in BV(\Omega)$, then for every $\epsilon > 0$ there exists a $w_\epsilon \in \mathcal{C}^\infty(\Omega)$ such that*

$$\|w - w_\epsilon\|_{L^1} \leq \epsilon |Dw|(\Omega), \quad \|\nabla w_\epsilon\|_{L^1} \leq (1 + c\epsilon) |Dw|(\Omega), \quad \|D^2 w_\epsilon\|_{L^1} \leq c\epsilon^{-1} |Dw|(\Omega).$$

Proof. Without loss of generality, we can assume that $0 \in \Omega$ and that Ω is star-shaped with respect to 0. For $\epsilon > 0$ we define

$$\Omega_\epsilon = \{y \in \mathbb{R}^d : y = (1 + \epsilon)x, x \in \Omega\},$$

and notice that Ω and Ω_ϵ are related via a bijective and Lipschitz, in fact linear, transformation with Lipschitz constant $1 + \epsilon$ and Jacobian $(1 + \epsilon)^d \leq 1 + c\epsilon$. For $w \in BV(\Omega)$ we define $v_\epsilon \in BV(\Omega_\epsilon)$ via $v_\epsilon(y) = w(\frac{y}{1+\epsilon})$ and, for $x \in \Omega$, $w_\epsilon(x) = v_\epsilon * \rho_\epsilon(x)$, where ρ_ϵ is a smooth convolution kernel such that, for ever $1 \leq p \leq \infty$, $\|\nabla \rho_\epsilon\|_{L^p} \leq c\epsilon^{-(1+d/p')}$ with $p' = p/(p-1)$.

If $w \in \mathcal{C}^1(\Omega)$ then, clearly, $\|w - w_\epsilon\|_{L^1} < \epsilon \|\nabla w\|_{L^1} = \epsilon |Dw|(\Omega)$ and

$$\|\nabla w_\epsilon\|_{L^1} \leq |Dv_\epsilon|(\Omega_\epsilon) \leq (1 + c\epsilon) \|\nabla w\|_{L^1} = (1 + c\epsilon) |Dw|(\Omega).$$

We now recall that smooth functions are dense in $BV(\Omega)$ under strict convergence, (cf. [1, 38]). In other words, given $w \in BV(\Omega)$ there is a sequence $\{w_n\}_{n \in \mathbb{N}} \subset \mathcal{C}^\infty(\Omega)$ such that

$$\lim_{n \rightarrow \infty} \|w - w_n\|_{L^1} = 0, \quad \limsup_{n \rightarrow \infty} |Dw_n|(\Omega) \leq |Dw|(\Omega).$$

Applying the argument given above to elements of this sequence and then passing to the limit we obtain the first two inequalities.

We use Young's inequality for convolutions [24, Proposition 8.7] to obtain

$$\|D^2 w_\epsilon\|_{L^1} \leq \|\nabla w_\epsilon\|_{L^1} \|\nabla \rho_\epsilon\|_{L^1} \leq c \frac{1 + c\epsilon}{\epsilon} |Dw|(\Omega) \leq \frac{c}{\epsilon} |Dw|(\Omega),$$

which concludes the proof. \square

REMARK 2.2 (Approximation in L^p -spaces). *Observe that, in the setting of Proposition 2.1, Young's inequality also implies*

$$\|D^2 w_\epsilon\|_{L^p} \leq \|\nabla w_\epsilon\|_{L^1} \|\nabla \rho_\epsilon\|_{L^p} \leq c\epsilon^{-(1+d/p')} |Dw|(\Omega),$$

for any $p \in [1, \infty]$ with $p' = p/(p-1)$. In the sequel, however, we shall avoid using this bound since it would lead to d -dependent error estimates.

3. The Total Variation Flow. Let us define the functional $\Psi : L^2(\Omega) \rightarrow \mathbb{R}$ by

$$\Psi(w) = \begin{cases} |Dw|(\Omega), & w \in L^2(\Omega) \cap BV(\Omega), \\ +\infty, & w \in L^2(\Omega) \setminus BV(\Omega), \end{cases} \quad (3.1)$$

It is not difficult to show that Ψ is convex and lower semicontinuous. Then, one can define the subdifferential of Ψ (see [2, 6, 8, 10, 18, 26, 27]) and study its subgradient flow, i.e., we seek for a function $u : [0, T] \rightarrow L^2(\Omega)$ such that

$$u_t \in -\partial\Psi(u), \quad (3.2)$$

or, equivalently,

$$\langle u_t, u - w \rangle + \Psi(u) - \Psi(w) \leq 0, \quad \forall w \in L^2(\Omega). \quad (3.3)$$

It is in this sense that (1.1) is going to be understood and analyzed. Existence of solutions to (3.2) can be obtained with the help of the theory of maximal monotone operators, see [6, 10].

REMARK 3.1 (Dirichlet boundary conditions). *The definition that we have provided corresponds to imposing Neumann boundary conditions as in (1.1). The issue of how to impose Dirichlet boundary conditions is a delicate one since the trace of a $BV(\Omega)$ function is in $L^1(\partial\Omega)$ (cf. [1, 38]). In addition, the functional (3.1) has linear growth, so that the only possible way to impose Dirichlet boundary conditions is with the relaxed energy $\Psi(w) + \int_{\partial\Omega} |w - g|$; see [2, 28] for details. The introduction of this additional non-differentiable term greatly complicates the analysis. However, in the particular situation when Ω is convex, the boundary data is time independent and continuous, i.e., $g(x, t) = g(x) \in C^0(\partial\Omega)$, and the initial data is compatible with the boundary data in the sense that $u_0|_{\partial\Omega} = g$, then the solution u to the subgradient flow with the relaxed energy satisfies $u(\cdot, t)|_{\partial\Omega} = g(\cdot)$, for all $t \in (0, T]$; see [28, Lemma 4.1]. This can be realized, for instance, in the case of homogeneous Dirichlet boundary conditions ($g \equiv 0$) and compactly supported initial data. Under this particular setting all the results we present will also hold.*

Reference [2, Theorem 2.16] shows that problem (3.2) possesses a L^d - L^∞ regularizing effect, that is if $u_0 \in L^d(\Omega)$, then $u(t) \in L^\infty(\Omega)$ for all $t > 0$. Let us show that solutions to this problem also satisfy a maximum principle.

THEOREM 3.2 (Maximum principle for TV flow). *Assume that $u_0 \in L^\infty(\Omega)$, then u , solution of (3.3), is such that $u \in L^\infty([0, T], L^\infty(\Omega))$ and*

$$\|u\|_{L^\infty(L^\infty)} \leq \|u_0\|_{L^\infty}.$$

Proof. Since $u_0 \in L^\infty(\Omega)$ we can define $\mathcal{U}_0 = \text{ess sup}_{x \in \Omega} u_0(x)$, and $\bar{w}(t) = u(t) \vee \mathcal{U}_0$. Since $\text{supp } D\bar{w} = \{x \in \Omega : u \geq \mathcal{U}_0\}$ and, on this set, $D\bar{w} = Du$, we can conclude that $\bar{w} \in L^2(\Omega) \cap BV(\Omega)$ and $\Psi(\bar{w}) \leq \Psi(u)$. Setting $w = \bar{w}$ in (3.3) we obtain $\langle u_t, 0 \vee (u - \mathcal{U}_0) \rangle \leq 0$, which, since \mathcal{U}_0 is constant, implies $\frac{d}{dt} \| (u - \mathcal{U}_0) \vee 0 \|_{L^2}^2 \leq 0$. Given that $(u_0 - \mathcal{U}_0) \vee 0 = 0$ this implies the result. \square

4. Discretization. In this section we introduce and analyze a fully discrete scheme for the approximation of solutions to (3.3). We begin with a semidiscrete (continuous in space and discrete in time) scheme for (3.3) which can then be analyzed using standard results from the literature (cf. [33, 35]). Then we develop a theory for fully discrete subgradient flows in Hilbert spaces and discuss the effect of introducing a discrete energy and a perturbation on the right hand side. We will provide sufficient compatibility conditions between the space discretization and the discrete energy to guarantee convergence. These results constitute a general and, as far as we know, novel approach to the study of fully discrete schemes for subgradient flows and evolution variational inequalities. The main application of these results will be, of course, a fully discrete scheme for (3.3).

4.1. A Semidiscrete Scheme for TV Flows. We introduce a sequence $\{u^{\Delta t}\}$ contained in $L^2(\Omega) \cap BV(\Omega)$ with $u^0 = u_0$ that solves:

$$\left\langle \frac{\delta u^{k+1}}{\Delta t}, u^{k+1} - w \right\rangle + \Psi(u^{k+1}) - \Psi(w) \leq 0 \quad \forall w \in L^2(\Omega). \quad (4.1)$$

Existence and uniqueness is guaranteed by the convexity and lower semicontinuity of Ψ ; see [2, 6, 10, 18]. *A priori* estimates, as well as a maximum principle are established in the next result.

PROPOSITION 4.1 (Semidiscrete stability). *Let $\{u^{\Delta t}\}$ solve (4.1). If $u^0 \in L^2(\Omega)$, then*

$$\|u^{\Delta t}\|_{\ell^\infty(L^2)}^2 + \|u^{\Delta t}\|_{\mathfrak{h}^{1/2}(L^2)}^2 + \Delta t \sum_{k=1}^K |Du^k|(\Omega) \leq c \|u^0\|_{L^2}^2. \quad (4.2)$$

If $u^0 \in L^2(\Omega) \cap BV(\Omega)$, then the flow is monotone, i.e., $\Psi(u^{k+1}) \leq \Psi(u^k) \leq \Psi(u^0)$ for all $k \geq 0$; and, moreover,

$$\|u^{\Delta t}\|_{\mathfrak{h}^{1/2}(L^2)}^2 + \Delta t \Psi(u^K) \leq \Delta t \Psi(u^0). \quad (4.3)$$

If $u^0 \in L^\infty(\Omega) \cap BV(\Omega)$, then $u^{\Delta t} \subset L^\infty(\Omega)$ and

$$\|u^{\Delta t}\|_{\ell^\infty(L^\infty)} \leq \|u^0\|_{L^\infty}.$$

Proof. To obtain (4.2) it suffices to set $w = 0$ on (4.1) and add over k . To obtain (4.3) we set $w = u^k$ and add over k . The maximum principle is obtained *mutatis mutandis* the proof of Theorem 3.2. \square

The convergence properties of (4.1) are a consequence of standard results [33, 35]. For convenience we summarize them below.

COROLLARY 4.2 (Convergence of semidiscrete TV flow). *Assume that $u^0 \in L^2(\Omega) \cap BV(\Omega)$, then*

$$\|u - \hat{u}\|_{L^\infty(L^2)}^2 + \Delta t \Psi(u^K) \leq c (\|u_0 - u_0\|_{L^2}^2 + \Delta t^\alpha),$$

where \hat{u} is the piecewise linear function defined in (2.4) and $\alpha = 1$. If, in addition, $\partial\Psi(u_0) \cap L^2(\Omega) \neq \emptyset$, then $\alpha = 2$.

REMARK 4.3 (Error estimates for semidiscrete flows). *Notice that the conclusion of Corollary 4.2 gives an error estimate of order $\mathcal{O}(\Delta t^{1/2})$ under the sole assumption that the initial condition has finite energy. Under this regularity the result is optimal, see [35, Theorem 5]. Observe also that the assumption $\partial\Psi(u_0) \cap L^2(\Omega) \neq \emptyset$, necessary to obtain a $\mathcal{O}(\Delta t)$ estimate, is not a regularity but rather a compatibility assumption. We refer the reader to [2] for a partial characterization of the subdifferential of the total variation.*

4.2. Fully Discrete Schemes for Subgradient Flows in Hilbert Spaces.

Here we present and analyze of a fully discrete implicit Euler method for subgradient flows in Hilbert spaces. The main novelty of our approach is the treatment of the space discretization and that we allow for perturbations of the energy, as well as of the right hand side.

Let H be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$, which induces the norm $\|\cdot\|_H$. Assume that the functional $\mathfrak{F} : \mathcal{D}(\mathfrak{F}) \subset H \rightarrow \mathbb{R}$ is convex, lower semicontinuous and $\overline{\mathcal{D}(\mathfrak{F})} = H$. Then, for every $w \in \mathcal{D}(\mathfrak{F})$ the subdifferential $\partial\mathfrak{F}(w) \subset H$ is not empty. For details we refer to [6, 10, 18]. We want to study its subgradient flow: Find $v : [0, T] \rightarrow H$ with $v|_{t=0} = v_0$, such that

$$v_t + \partial\mathfrak{F}(v) \ni 0, \quad (4.4)$$

or, equivalently,

$$\langle v_t, v - w \rangle + \mathfrak{F}(v) - \mathfrak{F}(w) \leq 0, \quad \forall w \in H. \quad (4.5)$$

The existence and uniqueness of a solution to (4.4) or (4.5) follows the theory of maximal monotone operators, [6, 10].

To discretize in time we consider the Euler method. In other words, we search for $v^{\Delta t} \subset H$, $v^0 = v_0$, such that

$$\left\langle \frac{\delta v^{k+1}}{\Delta t}, v^{k+1} - w \right\rangle + \mathfrak{F}(v^{k+1}) - \mathfrak{F}(w) \leq 0, \quad \forall w \in H. \quad (4.6)$$

The theory of [33, 35] provides, under the assumption that $v^0 \in \mathcal{D}(\mathfrak{F})$ a $\mathcal{O}(\Delta t^{1/2})$ error estimate as in Corollary 4.2.

We now introduce the space discretization. Let $\{\mathcal{H}_h\}_{h>0}$ be a family of (finite dimensional) subspaces of H . To be able to handle perturbations on the energy induced by the spatial discretization we assume that, for each $h > 0$, we have a convex and lower semicontinuous functional $\mathfrak{F}_h : \mathcal{H}_h \rightarrow \mathbb{R}$ that is *monotone*, in the sense that

$$\mathfrak{F}_h(w_h) \geq \mathfrak{F}(w_h), \quad \forall w_h \in \mathcal{H}_h. \quad (4.7)$$

Moreover, we assume that the spaces \mathcal{H}_h possess suitable approximation properties. In other words, there is a dense subspace $W \hookrightarrow H$, an operator $\mathcal{C}_h : W \rightarrow \mathcal{H}_h$ and functions $\varepsilon_i \in \mathcal{C}([0, \infty), [0, \infty))$, $\varepsilon_i(0) = 0$, $i = 1, 2$, such that

$$\|\mathcal{C}_h w - w\|_H \leq \varepsilon_1(h)\|w\|_W, \quad \forall w \in W, \quad (4.8)$$

and this approximation is *asymptotically energy diminishing*, i.e.,

$$\mathfrak{F}_h(\mathcal{C}_h w) - \mathfrak{F}(w) \leq \varepsilon_2(h)\|w\|_W, \quad \forall w \in W. \quad (4.9)$$

We consider the following fully discrete problem: Find $v_h^{\Delta t} \subset \mathcal{H}_h$ such that

$$\left\langle \frac{\delta v_h^{k+1}}{\Delta t}, v_h^{k+1} - w_h \right\rangle + \mathfrak{F}_h(v_h^{k+1}) - \mathfrak{F}_h(w_h) \leq \langle \rho^{k+1}, v_h^{k+1} - w_h \rangle, \quad (4.10)$$

for all $w_h \in \mathcal{H}_h$, where $\rho^{\Delta t} \subset H$ is a perturbation.

We begin our analysis of the fully discrete method (4.10) with an *a priori* bound on the increments of the sequence $v_h^{\Delta t}$.

LEMMA 4.4 (Stability of derivatives). *The solution $v_h^{\Delta t}$ to (4.10) satisfies*

$$\frac{1}{2} \|v_h^{\Delta t}\|_{\mathfrak{H}^{1/2}(H)}^2 + \Delta t \mathfrak{F}_h(v_h^K) \leq \Delta t \mathfrak{F}_h(v_h^0) + \frac{\Delta t}{2} \|\rho^{\Delta t}\|_{\ell^2(H)}^2.$$

Proof. Set $w_h = v_h^k$ in (4.10). Multiplying by Δt , adding over k , and using Young's inequality, we obtain the result. \square

The sequence $\rho^{\Delta t}$ is meant to be a perturbation induced by either discretization or the solution procedure. For this reason we shall assume that

$$\|\rho^{\Delta t}\|_{\ell^\infty(H)} \leq c \Delta t^{1/2}. \quad (4.11)$$

Based on this estimate, the error analysis proceeds as follows.

THEOREM 4.5 (A priori error analysis). *Let $v^{\Delta t}$ be the solution to (4.6) and $v_h^{\Delta t}$ the solution of (4.10). Assume $v^{\Delta t} \in \ell^\infty(W)$. If the operator \mathcal{C}_h satisfies (4.8) and (4.9); the discrete energies \mathfrak{F}_h satisfy (4.7); $\mathfrak{F}_h(v_h^0) < +\infty$ uniformly in h ; and the perturbations $\rho^{\Delta t}$ satisfy (4.11), then there exists a constant $c > 0$ proportional to T such that*

$$\|v^{\Delta t} - v_h^{\Delta t}\|_{\ell^\infty(H)}^2 \leq \|v^0 - v_h^0\|_H^2 + c(\varepsilon_1(h) + \varepsilon_2(h)) \|v^{\Delta t}\|_{\ell^\infty(W)} + c \Delta t.$$

Proof. To simplify notation, as usual, we will denote $e^k = v^k - v_h^k$. Set $w = v_h^{k+1}$ in (4.6) and $w_h = \mathcal{C}_h v^{k+1}$ in (4.10) and add the results. Using the monotonicity property (4.7) we obtain

$$\begin{aligned} \left\langle \frac{\delta e^{k+1}}{\Delta t}, e^{k+1} \right\rangle &\leq \mathfrak{F}_h(\mathcal{C}_h v^{k+1}) - \mathfrak{F}_h(v^{k+1}) - \langle \rho^{k+1}, e^{k+1} \rangle \\ &\quad + \langle \rho^{k+1}, v^{k+1} - \mathcal{C}_h v^{k+1} \rangle + \left\langle \frac{\delta v_h^{k+1}}{\Delta t}, \mathcal{C}_h v^{k+1} - v^{k+1} \right\rangle. \end{aligned}$$

Using Lemma 4.4 and (4.11) we obtain $\Delta t^{-1} \sum_{k=1}^K \|\delta v_h^k\|_H^2 \leq c$, whence (4.8) and (4.9) yield

$$\langle \delta e^{k+1}, e^{k+1} \rangle \leq c \Delta t [\varepsilon_2(h) + \varepsilon_1(h)] \|v^{k+1}\|_W + \Delta t \|\rho^{k+1}\|_H \|e^{k+1}\|_H.$$

Since the sequence $\|e^{\Delta t}\|_H$ is finite we can assume that its maximum is attained for $k = \kappa$. Summing the above inequality over $k = \overline{1, \kappa - 1}$ we deduce

$$\|e^\kappa\|_H^2 + \|\delta e^\kappa\|_H^2 \leq \|e^0\|_H^2 + c(\varepsilon_1(h) + \varepsilon_2(h)) \|v^{\Delta t}\|_{\ell^\infty(W)} + 2 \Delta t \|e^\kappa\|_H \sum_{k=1}^{\kappa} \|\rho^k\|_H.$$

An application of Young's inequality, together with assumption (4.11) allows us to conclude. \square

4.3. Fully Discrete Scheme for TV Flows. Let us specialize the ideas presented in §4.2 to the case of TV flows. To do so, we will work on the discrete spaces (2.6), define discrete energies and approximation operators, and verify that assumptions (4.7)–(4.9) are satisfied. The conclusion of Theorem 4.5 will then allow us to obtain error estimates.

In this setting, we consider the subgradient flow: Find $u_h^{\Delta t} \in \mathbb{V}_h$ that solves

$$\left\langle \frac{\delta u_h^{k+1}}{\Delta t}, u_h^{k+1} - w_h \right\rangle + \Psi_h(u_h^{k+1}) - \Psi_h(w_h) \leq 0, \quad \forall w_h \in \mathbb{V}_h. \quad (4.12)$$

The discrete energy is defined by

$$\Psi_h(w_h) = \sum_{T \in \mathcal{T}_h} \int_T \mathcal{I}_h |\nabla w_h|, \quad (4.13)$$

where the operator \mathcal{I}_h was defined in (2.7). Notice that we have effectively replaced the total variation seminorm by a quadrature formula. Indeed, we can rewrite Ψ_h as

$$\Psi_h(w_h) = \sum_{T \in \mathcal{T}_h} \sum_{j=1}^{\mathcal{N}_T} |\nabla w_h|(z_{j,T}) \int_T \lambda_{j,T}(z) dz = \sum_{T \in \mathcal{T}_h} |T| \sum_{j=1}^{\mathcal{N}_T} \omega_j |\nabla w_h|(z_{j,T}),$$

where $\lambda_{j,T}$ is the coordinate basis function associated with node $z_{j,T}$ and we denote the weights by $\omega_j = |T|^{-1} \int_T \lambda_{j,T}(z) dz$. Notice that this modification fits into the framework described in §4.2. Its utility will become clear in the following paragraph.

The approximation operator is defined as

$$\mathcal{C}_h w = \Pi_h w_\epsilon, \quad (4.14)$$

where Π_h is the Clément interpolation operator and w_ϵ denotes a regularization of w as in Proposition 2.1 with $\epsilon = h^{2/3}$. Proving error estimates reduces to verification of the hypotheses of §4.2.

COROLLARY 4.6 (Convergence of TV flow). *Let $u^{\Delta t}$ be the solution of (4.1) and $u_h^{\Delta t}$ the solution of (4.12) with the discrete energy given in (4.13). If Ω is star shaped with respect to a point; $u^0 \in L^\infty(\Omega) \cap BV(\Omega)$; and $\Psi_h(u_h^0) \leq c < +\infty$ uniformly in h , then*

$$\|u^{\Delta t} - u_h^{\Delta t}\|_{\ell^\infty(L^2)}^2 \leq \|u^0 - u_h^0\|_{L^2}^2 + ch^{1/3}.$$

Proof. Notice, first of all, that the given assumptions on u^0 translate into $u^{\Delta t} \in \ell^\infty(L^\infty(\Omega) \cap BV(\Omega))$. Consequently, we set $W = BV(\Omega) \cap L^\infty(\Omega)$ and

$$\|w\|_W = \|w\|_{L^\infty} + |Dw|(\Omega).$$

It suffices to verify the abstract assumptions (4.7)–(4.9):

(4.7): If $w_h|_T \in \mathbb{P}_1$, then ∇w_h is constant and $\mathcal{I}_h |\nabla w_h| = |\nabla w_h|$. If $w_h|_T \in \mathbb{Q}_1$ instead, then its gradient is linear and, consequently, $|\nabla w_h|$ is convex. Then, we only need to realize that if the function φ is convex, then $\mathcal{I}_h \varphi|_T \geq \varphi|_T$. Indeed, using that $\sum_{j=1}^{\mathcal{N}_T} \lambda_{j,T} \equiv 1$,

$$\mathcal{I}_h \varphi|_T(z) = \sum_{j=1}^{\mathcal{N}_T} \varphi(z_{j,T}) \lambda_{j,T}(z) \geq \varphi \left(\sum_{j=1}^{\mathcal{N}_T} z_{j,T} \lambda_{j,T}(z) \right) = \varphi(z).$$

(4.8): (2.1), together with the L^∞ -stability of Π_h , gives

$$\|\Pi_h w_\epsilon - w\|_{L^2}^2 \leq \|\Pi_h w_\epsilon - w\|_{L^1} \|\Pi_h w_\epsilon - w\|_{L^\infty} \leq c \|w\|_{L^\infty} \|\Pi_h w_\epsilon - w\|_{L^1}.$$

To bound the L^1 norm in the above inequality we add and subtract w_ϵ to obtain

$$\|\Pi_h w_\epsilon - w\|_{L^1} \leq \|\Pi_h w_\epsilon - w_\epsilon\|_{L^1} + \|w_\epsilon - w\|_{L^1} \leq c \left(\frac{h^2}{\epsilon} + \epsilon \right) |Dw|(\Omega),$$

where we have used (2.8), for $p = 1$, in conjunction with Proposition 2.1.

(4.9): We begin the proof of the energy diminishing property by

$$\begin{aligned} \Psi_h(\Pi_h w_\epsilon) - \Psi(w) &= \int_{\Omega} \mathcal{I}_h |\nabla \Pi_h w_\epsilon| - |Dw|(\Omega) \leq \\ &\left(\int_{\Omega} (\mathcal{I}_h |\nabla \Pi_h w_\epsilon| - |\nabla \Pi_h w_\epsilon|) \right) + \left(\int_{\Omega} (|\nabla \Pi_h w_\epsilon| - |\nabla w_\epsilon|) \right) + \\ &\left(\int_{\Omega} |\nabla w_\epsilon| - |Dw|(\Omega) \right) = I + II + III. \end{aligned}$$

Applying Proposition 2.1 yields $III \leq c\epsilon |Dw|(\Omega)$. We next invoke the triangle inequality along with interpolation estimate (2.8) for Π_h to arrive at

$$II \leq \int_{\Omega} |\nabla(\Pi_h w_\epsilon - w_\epsilon)| \leq ch \|D^2 w_\epsilon\|_{L^1} \leq c \frac{h}{\epsilon} |Dw|(\Omega).$$

For the first term I , we use (2.8) to obtain

$$I = \int_{\Omega} \mathcal{I}_h |\nabla \Pi_h w_\epsilon| - |\nabla \Pi_h w_\epsilon| \leq ch \sum_{T \in \mathcal{T}_h} \|\nabla(|\nabla \Pi_h w_\epsilon|)\|_{L^1(T)}.$$

For a smooth function,

$$\nabla(|\nabla f|) = \frac{\nabla f}{|\nabla f|} D^2 f, \quad \text{a.e. } \{x \in T : \nabla f(x) \neq 0\},$$

and $\nabla(|\nabla f|) = 0$ a.e. $\{x \in T : \nabla f = 0\}$. This allows us to conclude that $|\nabla(|\nabla f|)| \leq |D^2 f|$ a.e. in T . This, together with the bound (2.9) and Proposition 2.1, shows that

$$\int_{\Omega} \mathcal{I}_h |\nabla \Pi_h w_\epsilon| - |\nabla \Pi_h w_\epsilon| \leq ch \|D^2 w_\epsilon\|_{L^1} \leq c \frac{h}{\epsilon} |Dw|(\Omega).$$

The estimates above allow us to see that

$$\varepsilon_1(h) = c \left(\frac{h^2}{\epsilon} + \epsilon \right)^{1/2} \quad \varepsilon_2(h) = c \left(\frac{h}{\epsilon} + \epsilon \right).$$

Setting $\epsilon = h^{2/3}$ we obtain the result. \square

REMARK 4.7 (Energy diminishing interpolation). *The proof of Corollary 4.6 actually shows that if we were able to construct a TV diminishing interpolant, i.e., such that*

$$\int_{\Omega} |\nabla \mathcal{C}_h w| \leq |Dw|(\Omega),$$

then $\varepsilon_2(h) = ch\epsilon^{-1}$ and, setting $\epsilon = h^{1/2}$ we would improve the rate of convergence to $\mathcal{O}(h^{1/4})$. Under the assumption that $\Omega = (0, 1)^d$ and that the mesh is Cartesian, [32] presents such a construction.

5. An Iterative Scheme for the Fully Discrete Scheme. A practical algorithm for the solution of the discrete variational inequalities (4.12) would require identifying the elements of the subdifferential $\partial\Psi_h(u)$. In the continuous setting, relying on the results of [3], such identification is presented in [2]. Let us describe this identification without going into technical details. We introduce the space

$$\mathbf{X} = \{\mathbf{q} \in \mathbf{L}^\infty(\Omega) : \nabla \cdot \mathbf{q} \in L^2(\Omega), \mathbf{q} \cdot \mathbf{n} = 0\},$$

and stress that $w \in \partial\Psi(u)$ if and only if [2]

$$\Psi(u) = \int_{\Omega} wu, \quad \text{and} \quad \exists \mathbf{z} \in \mathbf{X} \cap \mathfrak{B}_1(\mathbf{L}^\infty(\Omega)) : w = -\nabla \cdot \mathbf{z}.$$

Notice that we can replace the first equality above by $\Psi(u) = \int_{\Omega} \mathbf{z} \cdot \mathbf{D}u$ [2]. This serves as motivation for the discrete energy Ψ_h given in (4.13). Indeed,

$$\begin{aligned} \Psi_h(w_h) &= \sum_{T \in \mathcal{T}_h} |T| \sum_{j=1}^{\mathcal{N}_T} \omega_j |\nabla w_h|(z_{j,T}) = \sum_{T \in \mathcal{T}_h} |T| \sum_{j=1}^{\mathcal{N}_T} \omega_j \sup_{\mathbf{q} \in \mathbb{R}^d: |\mathbf{q}| \leq 1} \nabla w_h(z_{j,T}) \cdot \mathbf{q} \\ &= \sup_{\mathbf{q}_h \in \mathbf{X}_h: \|\mathbf{q}_h\|_{\mathbf{X}_h} \leq 1} \langle \nabla w_h, \mathbf{q}_h \rangle_h = \sup_{\mathbf{q}_h \in \mathbf{X}_h} \{ \langle \nabla w_h, \mathbf{q}_h \rangle_h - \mathfrak{I}_{\mathfrak{B}_1(\mathbf{X}_h)}(\mathbf{q}_h) \}, \end{aligned}$$

where \mathfrak{I}_S denotes the indicator function of S , the discrete space \mathbf{X}_h is defined as

$$\mathbf{X}_h = \{\mathbf{q}_h \in \mathbf{L}^\infty(\Omega) : \mathbf{q}_h|_T \in \mathbb{Q}_1^d, \forall T \in \mathcal{T}_h\}, \quad \|\mathbf{q}_h\|_{\mathbf{X}_h} = \max_{T \in \mathcal{T}_h} \max_{j=1, \dots, \mathcal{N}_T} \{|\mathbf{q}_h(z_{j,T})|\},$$

and the discrete inner product $\langle \cdot, \cdot \rangle_h$ is defined by the quadrature rule

$$\langle \mathbf{q}_h, \mathbf{r}_h \rangle_h = \sum_{T \in \mathcal{T}_h} |T| \sum_{j=1}^{\mathcal{N}_T} \omega_j \mathbf{q}_h(z_{j,T}) \cdot \mathbf{r}_h(z_{j,T}).$$

The latter induces the norm $\|\mathbf{q}_h\|_h^2 = \langle \mathbf{q}_h, \mathbf{q}_h \rangle_h$, which clearly implies

$$\|\mathbf{q}_h\|_h \leq c \|\mathbf{q}_h\|_{\mathbf{L}^2}, \quad \forall \mathbf{q}_h \in \mathbf{X}_h. \quad (5.1)$$

In this setting it is not difficult to see that the fully discrete subgradient flow (4.12) with energy (4.13) is equivalent to finding $u_h^{\Delta t} \subset \mathbb{V}_h$ and $\mathbf{z}_h^{\Delta t} \subset \mathfrak{B}_1(\mathbf{X}_h)$ that solve:

$$\left\langle \frac{\delta u_h^{k+1}}{\Delta t}, w_h \right\rangle + \langle \mathbf{z}_h^{k+1}, \nabla w_h \rangle_h = 0, \quad \forall w_h \in \mathbb{V}_h, \quad (5.2)$$

and

$$\langle \mathbf{q}_h - \mathbf{z}_h^{k+1}, \nabla u_h^{k+1} \rangle_h \leq 0, \quad \forall \mathbf{q}_h \in \mathfrak{B}_1(\mathbf{X}_h). \quad (5.3)$$

5.1. Exact Solver. Problem (5.2)–(5.3) is not a practical numerical scheme, since it involves the solution of the (local) variational inequality (5.3). To overcome this difficulty we exploit that (5.2)–(5.3) are the optimality conditions of the functional $w_h \mapsto \frac{1}{2\Delta t} \|w_h - u_h^k\|_{L^2}^2 + \int_{\Omega} \mathcal{I}_h |\nabla w_h|$, which motivates the following algorithm for the

solution of (5.2)–(5.3) (cf. [7, 12]): Let $\sigma > 0$ and $\tau > 0$ be parameters to be chosen. Given $g_h = u_h^k \in \mathbb{V}_h$, set $v_h^0 = g_h$, $\lambda_h^0 = 0$ and find $\{v_h^\tau, \lambda_h^\tau\} \subset \mathbb{V}_h \times \mathfrak{B}_1(\mathbf{X}_h)$ by

$$\left\langle -\frac{\sigma}{\tau} \delta \lambda_h^{l+1} + \nabla v_h^{*,l+1}, \mathbf{q}_h - \lambda_h^{l+1} \right\rangle_h \leq 0 \quad \forall \mathbf{q}_h \in \mathfrak{B}_1(\mathbf{X}_h), \quad (5.4)$$

where $v_h^{*,l+1}$ is the extrapolation defined in (2.3), and

$$\left\langle \frac{\delta v_h^{l+1}}{\tau}, w_h \right\rangle + \left\langle \lambda_h^{l+1}, \nabla w_h \right\rangle_h + \frac{1}{\Delta t} \langle v_h^{l+1}, w_h \rangle = \frac{1}{\Delta t} \langle g_h, w_h \rangle. \quad (5.5)$$

Finally, set $u_h^{k+1} = v_h^\infty$.

The last assertion needs to be justified, this is given in the following.

THEOREM 5.1 (Convergence of the inner iterations). *Assume the inverse inequality $\|\nabla w_h\|_{L^2} \leq c_i h^{-1} \|w_h\|_{L^2}$ holds, and the parameters τ and σ are chosen so that $\tau \leq c_i \sigma h$. Then the inner iterative loop (5.4)–(5.5) converges, in the sense that for every $L \geq 1$,*

$$\sum_{l=0}^L \left(\frac{\tau}{\Delta t} \|u_h^{k+1} - v_h^{l+1}\|_{L^2}^2 + \frac{\sigma}{2} \|\delta \lambda_h^{l+1}\|_h^2 \right) \leq c.$$

Proof. We follow the arguments of [7, Proposition 3.1]. To alleviate the notation, set $e_h^l = u_h^{k+1} - v_h^l$ and $\mathbf{E}_h^l = \mathbf{z}_h^{k+1} - \lambda_h^l$. Subtract (5.5) from (5.2) to obtain

$$\left\langle \frac{\delta e_h^{l+1}}{\tau}, w_h \right\rangle + \langle \mathbf{E}_h^{l+1}, \nabla w_h \rangle_h + \frac{1}{\Delta t} \langle e_h^{l+1}, w_h \rangle = 0. \quad (5.6)$$

Set $\mathbf{q}_h = \mathbf{z}_h^{k+1}$ in (5.4), $\mathbf{q}_h = \lambda_h^{l+1}$ in (5.3) and add them, to obtain

$$-\left\langle -\frac{\sigma}{\tau} \delta \mathbf{E}_h^{l+1} + \nabla (u_h^{k+1} - v_h^{*,l+1}), \mathbf{E}_h^{l+1} \right\rangle_h \leq 0. \quad (5.7)$$

Set $w_h = 2\tau e_h^{l+1}$ in (5.6) to obtain

$$\delta \|e_h^{l+1}\|_{L^2}^2 + \|\delta e_h^{l+1}\|_{L^2}^2 + 2\tau \langle \mathbf{E}_h^{l+1}, \nabla e_h^{l+1} \rangle_h + \frac{2\tau}{\Delta t} \|e_h^{l+1}\|_{L^2}^2 \leq 0. \quad (5.8)$$

Multiply (5.7) by 2τ and add it to (5.8) and add over $l = \overline{0, L-1}$ to obtain

$$\begin{aligned} \|e_h^L\|_{L^2}^2 + \sigma \|\mathbf{E}_h^L\|_h^2 + \sum_{l=0}^{L-1} \left(\|\delta e_h^{l+1}\|_{L^2}^2 + \sigma \|\delta \mathbf{E}_h^{l+1}\|_h^2 + \frac{2\tau}{\Delta t} \|e_h^{l+1}\|_{L^2}^2 \right) \\ \leq \|e_h^0\|_{L^2}^2 + \sigma \|\mathbf{E}_h^0\|_h^2 + 2\tau \sum_{l=0}^{L-1} \langle \delta^2 \nabla e_h^{l+1}, \mathbf{E}_h^{l+1} \rangle_h. \end{aligned}$$

Now we proceed as in [7, Proposition 3.1] with the last term: we use (2.5) to sum by parts and next employ inequality (5.1), the inverse inequality and repeated applications of Cauchy-Schwarz to obtain the desired result. \square

REMARK 5.2 (Convergence of the Lagrange multiplier). *As already mentioned in [7, Remark 3.2(i)], convergence $\lambda_h^l \rightarrow \mathbf{z}_h^{k+1}$, as $l \rightarrow \infty$, cannot be expected in general,*

due to the non-uniqueness of \mathbf{z}_h^{k+1} . However the increments $\delta\boldsymbol{\lambda}_h^l$ converge to zero.

REMARK 5.3 (Solution of the discrete variational inequality). *It is not difficult to see that the solution to the discrete variational inequality (5.4) is explicit*

$$\boldsymbol{\lambda}_h^{l+1}(z_{j,T}) = \frac{\boldsymbol{\lambda}_h^l + \frac{\sigma}{\tau} \nabla v_h^{*,l+1}}{\max\{1, |\boldsymbol{\lambda}_h^l + \frac{\sigma}{\tau} \nabla v_h^{*,l+1}|(z_{j,T})\}}.$$

5.2. Inexact Solver. It is not feasible to iterate in (5.4)–(5.5) until convergence. For this reason we included in the analysis presented in §4.2 a perturbation term since if we were to stop after $L - 1$ iterations, (5.5) would become

$$\frac{1}{\Delta t} \langle v_h^L - u_h^k, w_h \rangle + \langle \boldsymbol{\lambda}_h^L, \nabla w_h \rangle_h = -\frac{1}{\tau} \langle \delta v_h^L, w_h \rangle,$$

and (5.4) would read

$$\langle \mathbf{r}_h^L + \nabla v_h^L, \mathbf{q}_h - \boldsymbol{\lambda}_h^L \rangle_h \leq 0,$$

with $\mathbf{r}_h^L = -\frac{\sigma}{\tau} \delta \boldsymbol{\lambda}_h^L - \delta^2 \nabla v_h^L$. Doing the formal replacements $v_h^L \leftarrow \tilde{u}_h^{k+1}$ and $\boldsymbol{\lambda}_h^L \leftarrow \tilde{\mathbf{z}}_h^{k+1}$ on the left hand side of these identities, setting $w_h = \tilde{u}_h^{k+1} - \tilde{w}_h$ and adding them we obtain

$$\left\langle \frac{\delta \tilde{u}_h^{k+1}}{\Delta t}, \tilde{u}_h^{k+1} - \tilde{w}_h \right\rangle + \tilde{\Psi}_h(\tilde{u}_h^{k+1}) - \tilde{\Psi}_h(\tilde{w}_h) \leq \left\langle -\frac{\delta v_h^L}{\tau}, \tilde{u}_h^{k+1} - \tilde{w}_h \right\rangle, \quad (5.9)$$

with

$$\tilde{\Psi}_h(w_h) = \sum_{T \in \mathcal{T}_h} \int_T \mathcal{I}_h |\nabla w_h + \mathbf{r}_h^L|.$$

The non-homogeneous term on the right hand side can be understood as a perturbation $\rho^{\Delta t}$. In addition, the modified discrete energies can be controlled owing to Theorem 5.1. We make these ideas rigorous in the following.

THEOREM 5.4 (Convergence of fully discrete scheme with inexact solutions). *Let Ω be star-shaped with respect to a point and assume that $\mathbf{u}_0 \in BV(\Omega) \cap L^\infty(\Omega)$. If $\{\tilde{u}_h^{\Delta t}, \tilde{\mathbf{z}}_h^{\Delta t}\} \subset \mathbb{V}_h \times \mathbf{X}_h$ are approximations to the solution of (5.2)–(5.3), computed with algorithm (5.4)–(5.5) in such a way that, for every time step k , the inequalities*

$$\|\tau^{-1} \delta v_h^L\|_{L^2} \leq c \Delta t^{1/2}, \quad \|\mathbf{r}_h^L\|_{L^1} \leq c \Delta t, \quad (5.10)$$

are satisfied, then the following error estimate holds

$$\left\| \mathbf{u} - \widehat{\tilde{u}_h^{k+1}} \right\|_{L^\infty(L^2)} \leq \|\mathbf{u}_0 - u_h^0\|_{L^2} + c(\Delta t^{1/2} + h^{1/6}).$$

The spatial rate of convergence becomes $\mathcal{O}(h^{1/4})$ as soon as $\Omega = (0, 1)^d$ and the mesh \mathcal{T}_h is Cartesian.

Proof. Since $\mathbf{u}_0 \in BV(\Omega) \cap L^\infty(\Omega)$, the solution, $u^{\Delta t}$, to (4.1) converges, with order $\mathcal{O}(\Delta t^{1/2})$, to the exact solution. This also guarantees, via Corollary 4.6, the convergence of $u_h^{\Delta t}$, solution of (4.12), to $u^{\Delta t}$ with order $\mathcal{O}(h^{1/6})$.

To study the convergence of $\tilde{u}_h^{\Delta t}$ to $u_h^{\Delta t}$ we proceed as in Theorem 4.5. Set $w_h = \tilde{u}_h^{k+1}$ in (4.12) and $\tilde{w}_h = u_h^{k+1}$ in (5.9) and add the result. On denoting $e_h^k = u_h^k - \tilde{u}_h^k$, we obtain

$$\frac{1}{\Delta t} \langle \delta e_h^{k+1}, e_h^{k+1} \rangle + \Psi_h(u_h^{k+1}) - \tilde{\Psi}_h(u_h^{k+1}) + \tilde{\Psi}_h(\tilde{u}_h^{k+1}) - \Psi_h(\tilde{u}_h^{k+1}) \leq \left\langle \frac{\delta v_h^L}{\tau}, e_h^{k+1} \right\rangle.$$

Since

$$\begin{aligned} \tilde{\Psi}_h(w_h) - \Psi_h(w_h) &= \sum_{T \in \mathcal{T}_h} \int_T (\mathcal{I}_h |\nabla w_h + \mathbf{r}_h^L| - \mathcal{I}_h |\nabla w_h|) \leq \sum_{T \in \mathcal{T}_h} \int_T \mathcal{I}_h |\mathbf{r}_h^L| \\ &\leq c \|\mathbf{r}_h^L\|_{L^1}, \end{aligned}$$

we notice that condition (5.10) suffices to guarantee that $\|e_h^{\Delta t}\|_{\ell^\infty(L^2)} \leq c\Delta t^{1/2}$. Conclude with a trivial application of the triangle inequality.

The improvement on the spatial rate of convergence is due to Remark 4.7. \square

6. Numerical Experiments. To illustrate the theory developed in the preceding sections, here we present a series of numerical experiments. We implemented scheme (5.4)–(5.5) where the stopping criterion for the inner iterations is given by (5.10). The implementation was done with the help of the `deal.II` library (see [4, 5]). Unless noted otherwise, we set $\Delta t = \frac{\sqrt{2}h}{10}$, $\tau = \Delta t$ and $\sigma = 0.1$.

6.1. The Characteristic of a Convex Set. Let $E \Subset \Omega \subset \mathbb{R}^2$, where E is convex, connected and of finite perimeter. Define $\lambda_E = \frac{P(E)}{|E|}$, where $P(E)$ stands for the perimeter of E . Assume, in addition, that $\partial E \in \mathcal{C}^{1,1}$ and that the curvature of E , \varkappa satisfies $\|\varkappa\|_{L^\infty(\partial E)} \leq \lambda_E$. Then, according to [2, 8], if $u_0 = \chi_E$ the solution to (3.2) with homogeneous Dirichlet boundary conditions is $u(x, t) = (1 - \lambda_E t)^+ \chi_E(x)$.

FIG. 6.1. $L^\infty(L^2)$ -errors for the evolution of the characteristic χ_B of a circle B with exact solution $u(x, t) = (1 - \lambda_B t)^+ \chi_B(x)$ and $\lambda_B = P(B)/|B|$, [2, 8] (see §6.1).

Figure 6.1 shows the $L^\infty(L^2)$ -error between the discrete and numerical solutions in the case when $\Omega = (-3, 3)^2$ and $E = B(0, 1)$. As we can see the behavior of the error is actually better (i.e., $\mathcal{O}(h^{1/2})$) than what our theory predicts.

6.2. The Characteristic of a Disconnected Set. With the setting of §6.1, references [2, 8] also show that if $u_0 = \sum_{i=1}^3 \chi_{B(x_i, r_i)}$, where the centers are at the vertices of an equilateral triangle of unit side-length and the radii satisfy $r_i \leq 0.2$, then $u(x, t) = \sum_{i=1}^3 (1 - \lambda_{B_i} t)^+ \chi_{B(x_i, r_i)}$.

FIG. 6.2. Evolution of the characteristic set of three balls $B_i = B(x_i, r_i)$ with centers x_i at the vertices of an equilateral triangle of unit size and radii $r_i \leq 0.2$. The exact solution is $u(x, t) = \sum_{i=1}^3 (1 - \lambda_{B_i} t)^+ \chi_{B(x_i, r_i)}$. The mesh is uniform with size $h = 2^{-5}$ and the time-step $\Delta t = \sqrt{2}h/10$. The discrete solution is shown every three time steps until extinction and preserves the structure of u without numerical diffusion and/or oscillations.

Figure 6.2 shows the evolution in this case when $h = 0.03$. Notice that our method provides a good approximation with relatively few nodes and it does not introduce spurious oscillations. In addition, we obtain fairly good agreement with the extinction time, given by $t_\star = \frac{1}{\lambda_B} = \frac{r}{2} = \frac{1}{10}$. In contrast to methods that involve regularization [21, 22], we observe consistency with the PDE in that the support of the fully discrete solution remains constant in time. Finally, the $L^\infty(L^2)$ -norm of the error with respect to h is shown in Figure 6.3. Again, we see that the error is $\mathcal{O}(h^{1/2})$.

6.3. The Characteristic of an Annulus. Again in the setting of §6.1, the evolution of $u_0 = M\chi_E$, where $E = B(0, R) \setminus \overline{B(0, r)}$ is an annulus and $M, R, r \in \mathbb{R}$,

FIG. 6.3. $L^\infty(L^2)$ -errors for the evolution of the characteristic of three circles (see §6.2). The observed convergence rate $\mathcal{O}(h^{1/2})$ is better than predicted by the theory.

$r < R$, is governed by [2, 8]

$$\mathbf{u}(x, t) = \begin{cases} \operatorname{sgn}(M)(|M| - \lambda_E t)^+ \chi_E + \lambda_{B(0,r)} t \chi_{B(0,r)}, & t < T_1, \\ \operatorname{sgn}(m)(|m| - \lambda_{B(0,r)}(t - T_1))^+ \chi_{B(0,R)}, & t \geq T_1, \end{cases}$$

with $T_1 = \frac{|M|}{\lambda_E + \lambda_{B(0,r)}}$ and $m = \lambda_{B(0,r)} T_1$.

We set $M = 4$, $R = 1/2$, $r = 1/4$. Figure 6.4 shows the evolution of the numerical solution for $h = 2^{-5}$ and notice that, in this case, $T_1 = 1/4$, $m = 2$ and the extinction time is $T_{ext} = 3/4$. Numerically we obtained $T_{1,h} \approx 0.2558$, $m_h \approx 2.045$, $T_{ext,h} \approx 0.796$; which are in good agreement with the exact values. In addition, we see that there is no diffusion, as opposed to what methods based on regularization obtain. The $L^\infty(L^2)$ -error with respect to h is presented in Figure 6.5. Again we obtain $\mathcal{O}(h^{1/2})$.

6.4. Convergence of the Inner Loop. The result of Theorem 5.1 guarantees convergence of the inner iteration at every step. However, there is no assessment of the speed of convergence. We numerically investigate the effect of the choice of initial condition for the inner loop. Set $\Omega = (-2, 2)$ and $\mathbf{u}_0 = \chi_{[-1,1]}$. We choose

$$\mathbf{z}_0^1 = 0, \quad \mathbf{z}_0^2 = \begin{cases} x + 2, & x \in (-2, -1), \\ -x, & x \in (-1, 1), \\ x - 2, & x \in (1, 2). \end{cases}$$

It is possible to show that only $\mathbf{z}_0^2 \in \partial\Psi(\mathbf{u}_0)$. For $h = 2^{-6}$, $\Delta t = \tau = h/10$ and $\sigma = 1$, Figure 6.6 plots the number of iterations as a function of the step for \mathbf{z}_0^1 and \mathbf{z}_0^2 . The number of initial iteration is much higher (more than 5000) for \mathbf{z}_0^1 than for \mathbf{z}_0^2 . Moreover, notice the spike on both graphs at 79 steps. This is due to the fact that, at this step, extinction occurs. From this we conclude that the number of iterations heavily depends on the initial choice of \mathbf{z}_0 or, more generally, on $\boldsymbol{\lambda}_h^0$. Strategies for choosing it need further investigation.

6.5. Comparison with Regularized Flow. To conclude our discussion, it is imperative to make a comparison between our method and those that involve regularization and show that the advantages in our approach are numerous. Before embarking in such an endeavor, let us recall some properties of regularized flows. The analysis developed in [22] does not provide a clear understanding of the relation between the

FIG. 6.4. *Evolution of the characteristic of a ring $E = B(0, R) \setminus \overline{B(0, r)}$ with $R = 1/2$ and $r = 1/4$. The mesh is uniform with size $h = 2^{-5}$ and the time-step $\Delta t = \sqrt{2}h/10$. The discrete solution, shown after 0, 18, 26, 50, 52, 72, 90, 108 and 170 time steps, reproduces well the form of the exact solution without numerical diffusion. The sealed characteristic $\chi_{B(0, R)}$ decreases whereas $\chi_{B(0, r)}$ increases until their heights merge and $\chi_{B(0, R)}$ continues to decrease.*

regularization ϵ and the space discretization h . By means of numerical experiments the authors conclude that $\epsilon = \mathcal{O}(h^2)$ is the optimal scaling law, see [22, Figures 4–5].

Let us, with the help of the theory developed in §4.2, try to bring some light into this matter. If we denote by u_ϵ the solution to (1.1) with regularization $\Psi_\epsilon(w) = \int_\Omega \sqrt{\epsilon^2 + |\nabla w|^2}$ given by (1.2), [22, Theorem 2] shows that

$$\|u - u_\epsilon\|_{L^\infty(L^2)} \leq c\epsilon^{1/2}. \quad (6.1)$$

If $u_{\epsilon, h}^{\Delta t} \subset \mathbb{V}_h$ is the solution to a fully discrete approximation of the regularized flow with $\Psi_{\epsilon, h} = \Psi_\epsilon$, under the assumption that $u_\epsilon \in L^\infty(0, T; H^2(\Omega))$ we have

$$\|u_\epsilon - \hat{u}_{\epsilon, h}^{\Delta t}\|_{L^\infty(L^2)} \leq c \left(\Delta t^{1/2} + h^{1/2} \epsilon^{-\alpha/2} \right). \quad (6.2)$$

To see this it suffices to realize that (4.7) is trivially satisfied and, setting $\mathcal{C}_h = \Pi_h$ we conclude that (4.8) amounts to

$$\|\mathcal{I}_h w - w\|_{L^2} \leq ch^2 \|w\|_{H^2} \implies \varepsilon_1(h) = ch^2 \|w\|_{H^2},$$

FIG. 6.5. $L^\infty(L^2)$ -errors for the evolution of the characteristic of a ring (see §6.3). The experimental convergence rate $\mathcal{O}(h^{1/2})$ is better than predicted.

FIG. 6.6. Number of iterations. Left: the initial dual variable is not in the subdifferential of the initial data, which requires more than 5000 initial iterations for convergence. Right: the initial dual variable is in the subdifferential, which entails fewer initial iterations for convergence (see §6.4).

and, since

$$\int_{\Omega} \left| \sqrt{\epsilon^2 + |\nabla w_1|^2} - \sqrt{\epsilon^2 + |\nabla w_2|^2} \right| \leq \int_{\Omega} |\nabla(w_1 - w_2)|,$$

we have, for (4.9),

$$\varepsilon_2(h) \leq ch \|w\|_{W_1^2}.$$

Finally, [21, Theorem 1.2] shows that $\|u_\epsilon\|_{L^2(H^2)} \leq \epsilon^{-\alpha}$ for some $\alpha \in \mathbb{N}_0$. Combining (6.1) and (6.2) with Theorem 4.5 we conclude

$$\|u - \hat{u}_{\epsilon,h}^{\Delta t}\|_{L^\infty(L^2)} \leq c \left(\Delta t^{1/2} + \epsilon^{1/2} + h\epsilon^{-\alpha/2} + h^{1/2} \right), \quad (6.3)$$

which yields the optimal scaling $\epsilon = \mathcal{O}(h^{\frac{2}{1+\alpha}})$.

The last ingredient we need to make the comparison is to recall that (cf. [28, Remark 5.3]) in the one dimensional case, i.e., $d = 1$, if the initial data is monotone, it is itself a minimizer of the total variation energy, and so the flow fixes it. In other words, if u_0 is monotone, then $u(t) = u_0$ for all $t > 0$.

Consider, in $\Omega = (0, 1)$, the initial data

$$u_0(x) = \begin{cases} 0, & x \leq \frac{1}{2}, \\ x - \frac{1}{2}, & \frac{1}{2} < x \leq 1. \end{cases}$$

FIG. 6.7. Solution, at $T = 5$, of the TV flow with monotone initial data. Our method (red with +), regularized flow with $\epsilon = h$ (blue with \times) and with $\epsilon = h^2$ (magenta with $*$). $h = 2^{-5}$, $\Delta t = 2^{-10}$. The unregularized solution coincides with the exact solution, whereas the regularized flow misses it, although it belongs to the discrete space.

According to the discussion presented above, the solution to (3.2) is $u(t) = u_0$. Figure 6.7 shows the solution, at $T = 5$, obtained with our method and the regularized flow with $\epsilon = \mathcal{O}(h^2)$ and $\epsilon = \mathcal{O}(h)$. The first choice is the one advocated in [22]; while the second is the optimal according to (6.3) provided $\alpha = 1$, which is consistent with Proposition 2.1. In such a case, (6.3) gives the following error estimate

$$\|u - \hat{u}_{\epsilon,h}^{\Delta t}\|_{L^\infty(L^2)} \leq ch^{1/2},$$

provided $\epsilon \approx h \approx \Delta t$. The mesh size is $h = 2^{-5}$ and the time-step $\Delta t = 2^{-10}$. Notice that the requirement $\Delta t = \mathcal{O}(h^2)$, which is needed for L^2 -convergence in the regularized flow (cf. [22, Theorem 4] and [21, Theorem 1.7]), is satisfied.

The advantages of our method are now evident. We do not impose any restriction on the time-step, as opposed to the $\Delta t = \mathcal{O}(h^2)$ that is necessary in regularized methods to guarantee convergence in $L^2(\Omega)$. Even if one is willing to settle for convergence in $L^p(\Omega)$, with $p < d/(d-1)$, the methods with regularization require that the solution of the regularized flow is in $L^\infty(0, T; W_1^1(\Omega)) \cap L^\infty(0, T; H_{\text{loc}}^1(\Omega))$. If an error estimate is desired, one must impose that $u_0 \in C^2(\bar{\Omega})$, and even in that case it is not clear what is the relation between h , Δt and ϵ . In addition to these approximation issues, the regularized flow requires the solution, at each time step, of a nonlinear system and no convergence analysis is provided. In contrast, we have developed and analyzed an inexact iterative scheme for the solution of our problems at each time step, and we have showed its global convergence. To finalize, the result presented in Figure 6.7 shows that the regularized flow misses certain fundamental features of the problem, even in simple cases.

7. Total Variation Minimization. We conclude with yet another application of our result on approximation of functions of bounded variation (Proposition 2.1): we improve on the existing results about total variation minimization. Let $g \in L^\infty(\Omega)$ and $\alpha > 0$. Consider $\Xi(w) = \Psi(w) + \frac{\alpha}{2}\|w - g\|_{L^2}^2$. Thanks to the fact that this functional is strictly convex there exists a unique $\xi \in BV(\Omega) \cap L^2(\Omega)$ such that

$$\Xi(\xi) = \inf \{ \Xi(w) : w \in L^2(\Omega) \} < \infty. \quad (7.1)$$

Here we are interested in the approximation of ξ by elements of \mathbb{V}_h . Since \mathbb{V}_h is finite dimensional, there is a unique $\xi_h \in \mathbb{V}_h$ such that

$$\Xi(\xi_h) = \inf \{ \Xi(w_h) : w_h \in \mathbb{V}_h \} < \infty. \quad (7.2)$$

The main approximation properties of ξ_h are detailed in the following.

THEOREM 7.1 (Convergence of discrete minimizers). *Assume that Ω is star shaped with respect to a point. Let $\xi \in BV(\Omega) \cap L^\infty(\Omega)$ and $\xi_h \in \mathbb{V}_h$ be defined as in (7.1) and (7.2), respectively. Then*

$$\|\xi - \xi_h\|_{L^2} \leq ch^{1/4}.$$

Proof. We adapt the ideas presented in [7, Theorem 3.1]. Let $\epsilon > 0$ and $\xi_\epsilon \in \mathcal{C}^\infty(\Omega)$ be an approximation of ξ that satisfies all the properties stated in Proposition 2.1. Owing to the strict convexity of Ξ and the fact that ξ_h is a discrete minimizer, we have

$$\begin{aligned} \frac{\alpha}{2} \|\xi - \xi_h\|_{L^2}^2 &\leq \Xi(\xi_h) - \Xi(\xi) \leq \Xi(\Pi_h \xi_\epsilon) - \Xi(\xi) \\ &= (\|\nabla \Pi_h \xi_\epsilon\|_{L^1} - |\mathrm{D}\xi|(\Omega)) + \frac{\alpha}{2} (\|\Pi_h \xi_\epsilon - g\|_{L^2}^2 - \|\xi - g\|_{L^2}^2) = \mathcal{A}_1 + \mathcal{A}_2, \end{aligned}$$

where Π_h is the Clément interpolation operator [15]. Let us look at each one of the terms in this last inequality:

\mathcal{A}_1 : We add and subtract the W_1^1 -seminorm of ξ_ϵ and use its approximation properties with respect to total variation along with the approximation properties of Π_h described in (2.8):

$$\mathcal{A}_1 \leq \|\nabla(\Pi_h \xi_\epsilon - \xi_\epsilon)\|_{L^1} + \|\nabla \xi_\epsilon\|_{L^1} - |\mathrm{D}\xi|(\Omega) \leq c \left(\frac{h}{\epsilon} + \epsilon \right) |\mathrm{D}\xi|(\Omega).$$

\mathcal{A}_2 : We, again, use the approximation properties of ξ_ϵ and the fact that ξ and g are essentially bounded, say by a constant $c > 0$,

$$\mathcal{A}_2 \leq \frac{c\alpha}{2} (\|\mathcal{I}_h \xi_\epsilon - \xi_\epsilon\|_{L^1} + \|\xi_\epsilon - \xi\|_{L^1}) \leq c \left(\frac{h^2}{\epsilon} + \epsilon \right) |\mathrm{D}\xi|(\Omega).$$

Setting $\epsilon = h^{\frac{1}{2}}$ we obtain the result. \square

REMARK 7.2 (Convergence of total variation minimization). *Theorem 7.1 is, in a sense, an improvement over the original result of [7], at least for star shaped domains, and under the boundedness assumptions on g and ξ . If $\xi \in B_\infty^s(L^2(\Omega))$ for some $s \in (0, 1]$, and relying on the results of [37], [7, Theorem 3.1] proves the estimate*

$$\|\xi - \xi_h\|_{L^2} \leq ch^{\frac{s}{2(1+s)}},$$

so that the best possible rate of convergence is $\mathcal{O}(h^{1/4})$, which is what we obtain, but with lower regularity. To understand this regularity assumption it suffices to recall that $BV(\Omega) \cap L^\infty(\Omega) \hookrightarrow B_\infty^s(L^2(\Omega))$ for $s \leq \frac{1}{2}$ (see [36, Lemma 38.1] for a proof and, in some sense, the converse inclusion). The key step that allowed us to reduce the smoothness assumption is Proposition 2.1. In addition, the proof of Theorem 7.1 shows that if we had a TV-diminishing interpolant, we would obtain

$$\|\xi - \xi_h\|_{L^2} \leq ch^{1/2},$$

which is an optimal error estimate for $\xi \in B_\infty^s(L^2(\Omega))$. Such a construction is presented in [32].
